1 Project Background

In this modern age, having a loan provides individual the access to cash for purchasing and gain ownership on assets instantly. In exchange, the individual will bear the financial commitment with a repayment of principal and interest to the lender over the years. However, giving out loan is a risky business to the lender as it imposes credit risk when borrowers fail to repay their loans, resulting in loan default. Thus, credit scoring plays a vital role in allowing lenders to assess the risk prior to approving any loan application, especially in recent years with the dramatic growth in consumer credit.

Credit scoring is a score that represents the likelihood of an individual repaying loans. It is a formal statistical method used for differentiating credit applicants into ‘good’ and ‘bad’ risk classes (Li et al., 2004).

From a borrower’s standpoint, building a good credit scoring will not only allow their loan application to get approved easier as compared to a riskier borrower, but it also qualifies borrowers for lower interest rates. Having a good credit score reflects the individual as a trustworthy borrower and thus would enjoy more offers and rewards. Without a good credit score, it makes individuals vulnerable in getting funds for unexpected financial emergencies that would likely experience greater financial distress.

A few decades ago, financial institutions granted credit to individuals based on human judgement on loan default and experience in the industry (Hand & Henley, 1997). However, with the emergence of underwriting technologies and the economic pressure from the surging credit demand, financial institutions started to develop and leverage on credit scoring as a statistical model for making credit granting decisions. This shows a transition of assessment and pricing credit risk that are more data driven. With credit scoring classification, it optimizes financial institutions the ability to screen high-risk borrowers and target more generous facilities to lower-risk borrowers. These in turn enable financial institutions in minimizing default cost while increasing sales probability and overall expected profits (Einav et al., 2013).

2 Analysis Goal

In this project, we aim to predict the credit score of customers by leveraging their credit-related information, thus enabling finance companies to evaluate the customer’s credit risk level. The analysis will be performed and visualized based on data mining steps developed by SAS institute named SEMMA, which follows with the process sequence of Sample, Explore, Modify, Model and Assess.

Therefore, the objectives of this project are:

1. To explore the key factors that have significant impact on an individual’s credit score.
2. To build a credit score classification model.
3. To assess various models and determine the best model in classifying customers’ credit score.

3 Accessing and Assaying Prepared Data

3.1 Data Acquisition

The datasets were acquired from <https://www.kaggle.com/datasets/parisrohan/credit-score-classification?resource=download>. It was uploaded by Rohan Paris in July 2022 under the title

‘Credit score classification’. The purpose of the datasets was to create a machine learning model that can categorize the credit score when given information about a person’s credit history. Only the training dataset (train.csv) was chosen to be used in the model creation as it has the column denoting the credit score. The testing dataset (test.csv) will be used during the testing phase of our models.

3.2 Analysis of Data (Number of attributes/rows, anomalies, target features)

There are 28 attributes in the training dataset and 27 in the test dataset, with the credit score column being the difference. The training dataset has 100,000 rows while the testing dataset has 50,000 rows. The training dataset spans from January to August for each customer while the testing dataset covers the rest of the year, from September to December. Both datasets have a total of 12,500 unique customers and their data. The target feature of the data is the credit score which has three classifications, namely Poor, Standard, or Good.

3.3 Column Metadata

Table 3.3.1 below describes the columns in the datasets.

Column	Description
ID	Represents a unique identification of an entry
Customer_ID	Represents a unique identification of a person
Month	Represents the month of the year
Name	Represents the name of a person
Age	Represents the age of the person
SSN	Represents the social security number of a person
Occupation	Represents the occupation of the person
Annual_Income	Represents the annual income of the person
Monthly_Inhand_Salary	Represents the monthly base salary of a person
Num_Bank_Accounts	Represents the number of bank accounts a person holds
Num_Credit_Card	Represents the number of other credit cards held by a person
Interest_Rate	Represents the interest rate on credit card
Num_of_Loan	Represents the number of loans taken from the bank
Type_of_Loan	Represents the types of loan taken by a person
Delay_from_due_date	Represents the average number of days delayed from the payment date
Num_of_Delayed_Paymen	Represents the average number of payments delayed by a person
Changed_Credit_Limit	Represents the percentage change in credit card limit
Num_Credit_Inquiries	Represents the number of credit card inquiries
Credit_Mix	Represents the classification of the mix of credits
Outstanding_Debt	Represents the remaining debt to be paid (in USD)
Credit_Utilization_Ratio	Represents the utilization ratio of credit card
Credit_History_Age	Represents the age of credit history of the person
Payment_of_Min_Amount	Represents whether only the minimum amount was paid by the person

Total_EMI_per_month	Represents the monthly EMI payments (in USD)
Amount_invested_monthly	Represents the monthly amount invested by the customer (in USD)
Payment_Behaviour	Represents the payment behavior of the customer (in USD)
Monthly_Balance	Represents the monthly balance amount of the customer (in USD)
Credit_Score	Represents the bracket of credit score (Poor, Standard, Good)

Table 3.3.1 Column Metadata

4 Methodology: SEMMA

SAS Institute demonstrates data mining using the SEMMA methodology to uncover hidden information from massive amounts of data and improve business decision-making. The SEMMA process is well-known in handling business problems across various sectors as it aids businesses to gain a competitive edge, enhance performance, and provide customers with more beneficial services. Figure 4.1.1 below illustrates each phase in SEMMA in detail.

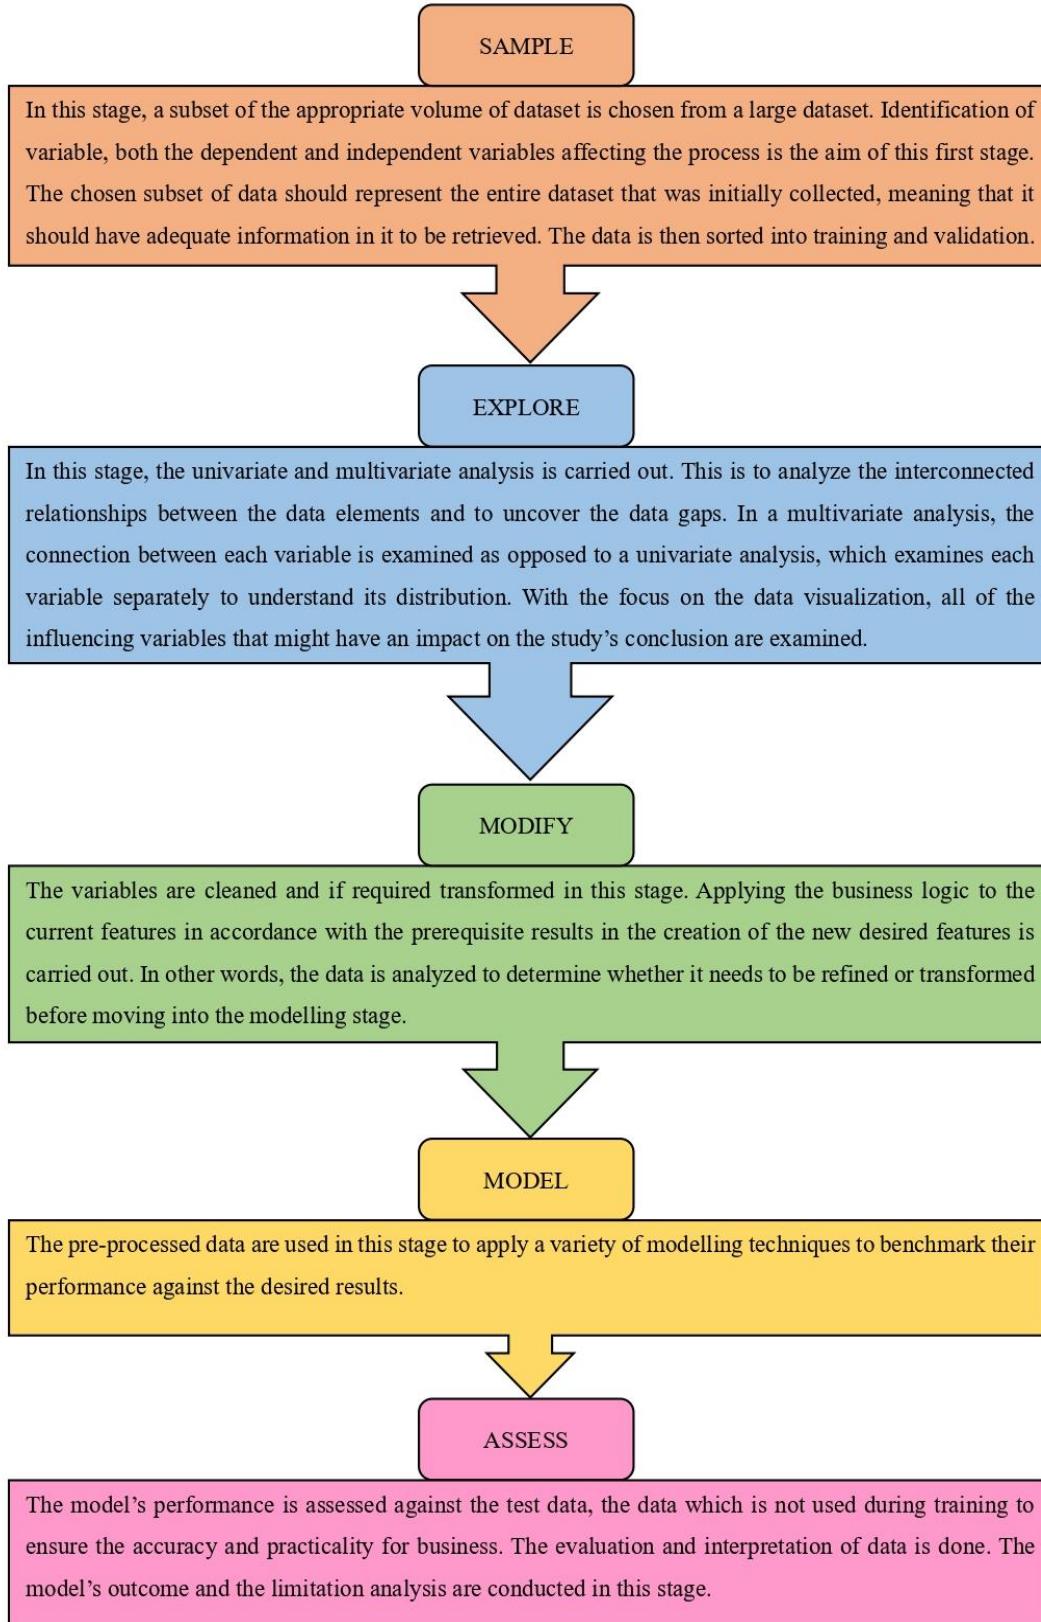

Figure 4.1.1 SEMMA

4.1 Project Setup

Setting up a new SAS Enterprise Miner project is required prior to applying the SEMMA process on the dataset. The step-by-step details include creating project, diagram, and library, and importing dataset are shown and described in the diagrams below.

1. A new SAS Enterprise Miner project is created by setting the project name “Credit Score Classification” and location of the project (Figures 12.1.1 - 12.1.4).
2. A SAS Enterprise Miner diagram workspace named “SE” is created to contain and display the steps involved in this project (Figures 12.1.5 - 12.1.6).
3. The training dataset, “train.csv” is uploaded to SAS server via SAS Studio located in SAS On Demand for Academics by selecting the “Upload” button to browse from local files. The uploaded dataset is ready for access in SAS Enterprise Miner to perform sampling and exploring techniques (Figures 12.1.7 - 12.1.11).
4. The File Import node located on the Sample tab of the toolbar is dragged to the SE diagram workspace to import the dataset from SAS server to SAS Enterprise Miner (Figures 12.1.12 - 12.1.18).
5. After importing the dataset, the Save Data node in the Utility tab is dragged to the SE diagram, then connected to the File Import node to save the dataset as a SAS table (Figures 12.1.19 - 12.1.23).
6. A library named “Dataset” is created with its path set as the location of the saved dataset to store the dataset (Figures 12.1.24 - 12.1.27).

5 SEMMA: SAMPLE

Once the project setup is completed, the dataset is ready for sampling process. The following describes the steps involved in the Sample stage, starting from creating and loading data sources to data sampling.

1. The data source is created via the Data Source Wizard by first setting the source as SAS Table (Figures 12.2.1 - 12.2.2).
2. The SAS table named “Em_save_train” located in the “Dataset” library is selected as our data source (Figures 12.2.3 - 12.2.6).
3. The information of the chosen data source like table name, number of variable and observations are displayed as shown in (Figure 12.2.7).
4. The advanced setting is used to modify the initial measurement levels and roles of the variables in the data source (Figure 12.2.8).
5. The figures below show the default setting (Figure 12.2.9) and modified setting (Figure 12.2.10) of the measurement levels and roles, respectively.

Figure 5.1.1 below demonstrates and highlights the modifications applied to the column metadata, especially on the reclassification of variables role and level. The Customer ID and SSN variables are dropped as they are not required for exploring and modelling stage later.

Variables	Role	Level
Age	Input	Nominal
Amount_invested_monthly	Input	Nominal
Annual_Income	Input	Nominal

Total_EMI_per_month	Input	Interval
Type_of_Loan	Input	Nominal

Figure 5.1.1 Reclassification of Variables Roles and Level

However, the level of the variables after reclassification still does not reflect the actual situation due to dirty and noisy data in the dataset. The variables level can only be classified accurately after the data cleaning process which will be applied at Modify stage in the next project phase. Figure 5.1.2 below demonstrates the correct level of variables of dataset.

Variables	Level
Age	Nominal
Amount_invested_monthly	Interval
Annual_Income	Interval
Changed_Credit_Limit	Interval
Credit_History_Age	Ordinal
Credit_Mix	Ordinal
Credit_Score	Ordinal
Credit_Utilization_Ratio	Interval
Customer_ID	Nominal

Outstanding_Debt	Interval
Payment_Behaviour	Nominal
Payment_of_Min_Amount	Nominal
SSN	Nominal
Total_EMI_per_month	Interval
Type_of_Loan	Nominal

Figure 5.1.2 Correct Variables Level

6. The decision processing is not specified as illustrated in (Figure 12.2.11).
7. The sample dataset is not created via the Data Source Wizard (Figure 12.2.12), but instead the data sampling process is applied after defining the data source (where detailed discussion is provided at point 12).
8. No changes have been made to the name and role of the data source (Figure 12.2.13).
9. The summary of the data source is shown in (Figure 12.2.14). As observed, there are 16 nominal variables (1 ID, 13 Input, 2 Rejected), 9 interval variables with Input role and 3 ordinal variables (2 Input, 1 Target) in the dataset.
10. The data source named “EM_SAVE_TRAIN” is created successfully and dragged to the SE diagram (Figures 12.2.15 - 12.2.17).
11. The node is then renamed to “Training Data” and ready for data sampling (Figures 12.2.18 - 12.2.22).
12. Data sampling is performed by dragging the Sample node in the Sample tab (Figures 12.2.23 - 12.2.24) to the SE diagram and connecting it to the “Training Data” node. The stratified equal-sized sampling method is applied with a random seed 12345, and the size of the training dataset is set to 30% (Figures 12.2.25 - 12.2.29).

6 SEMMA: EXPLORE

In the Explore phase, data exploration is performed to identify patterns, trends, and relationship between variables, as well as discover anomalies and outliers in the dataset that require further investigation in later phase. Common Exploratory Data Analysis (EDA) techniques include summary statistics, univariate, bivariate and multivariate analysis are applied using the nodes under the Explore tab in SAS Enterprise Miner. The findings of the analyses are discussed in detail later in this section, alongside some screenshots of SAS Enterprise Miner.

6.1 Statistical Summary

To generate the summary statistics of the dataset, the StatExplore node is used by dragging the node to the SE diagram and connecting to the Sample node (Figures 12.3.1 - 12.3.4). Figure 6.1.1 below shows the summary statistics of the class variables while Figure 6.1.2 below shows the summary statistics of the interval variables.

Class Variable Summary Statistics (maximum 500 observations printed)								
Data Role=TRAIN								
Data Role	Variable Name	Role	Number of			Mode Percentage	Mode2	Mode2 Percentage
			Levels	Missing	Mode			
TRAIN	Age	INPUT	513	0	25	2.95	28	2.94
TRAIN	Amount_invested_monthly	INPUT	513	19	10000	4.50		3.42
TRAIN	Annual_Income	INPUT	513	0	12613.56	0.61	75881.16	0.61
TRAIN	Changed_Credit_Limit	INPUT	513	0	-	3.11	5.71	0.86
TRAIN	Credit_History_Age	INPUT	404	0	NA	9.10	15_Years_and_11_Months	0.53
TRAIN	Credit_Mix	INPUT	4	0	Good	32.16	Standard	29.42

TRAIN	Credit_Score	TARGET	3	0	Good	33.33	Poor	33.33

Figure 6.1.1 Class Variables Summary Statistics

Based on Figure 6.1.1, there are 14 class variables and out of these variables, 11 of them do not contain missing values, whereas the Amount invested monthly, Num of Delayed Payment, and Type of Loan variables have missing values. It is noticeable that the Age, Amount invested monthly, Annual Income, Changed Credit Limit, Credit History Age, Num of Delayed Payment, Num of Loan, and Type of Loan variables have extremely high number of levels due to dirty and noisy data, and large numbers of distinct values. The Age, Amount invested monthly, Annual Income, Changed Credit Limit, Credit History Age, Num of Delayed Payment, and Num of Loan variables are classified as class variables, which are supposed to be classified as interval variables. The Type of Loan variable possess high cardinality, and high dimensional data can result in a range of issues such as overfitting, low model performance and interpretability. These issues will be properly addressed and discussed further in the Modify phase.

Interval Variable Summary Statistics (maximum 500 observations printed)												
Data Role=TRAIN												
Variable	Role	Mean	Standard Deviation	Non Missing	Missing	Non Missing	Minimum	Median	Maximum	Skewness	Kurtosis	
Credit_Utilization_Ratio	INPUT	32.28744	5.135271	30000	0	20.25707	32.3135	50	0.041792	-0.93116

Total_EMIs_per_month	INPUT	1432.826	8401.09	30000	0	0	70.58768	82236	7.04676	51.34881		

Figure 6.1.2 Interval Variable Summary Statistics

Based on Figure 6.1.2, the Monthly Balance, Monthly Inhand Salary, and Num Credit Inquiries variables have missing values, while the remaining 6 variables have no missing values. It is not reasonable that the Delay from due date and the Num Bank Accounts variables contain negative values (with minimum values -5 and -1 respectively), and the Num Bank Accounts, Num Credit Card and Interest rate variables have extremely high values (with maximum values 1798, 1499 and 5775 respectively).

Figure 6.1.3 Overview of Data

Based on Figure 6.1.3, some of the numerical variables such as the Age variable consists of ‘_’ character, which makes it unable to classify as interval variable, but instead character variable. In fact, the Credit History Age variable consists of missing values, but the missing values are labelled as ‘NA’ that is not recognized as missing values in SAS Enterprise Miner. Furthermore, the Payment of Min Amount column has a new label besides the ‘Yes’ and ‘No’ label, and the Credit Mix column also contains ‘_’ character in the data. All missing values, noisy and inconsistent data will be cleaned and transformed in the next phase.

6.2 Graph Visualization

In the graph visualization, univariate, bivariate and multivariate analysis are performed. The data exploration will not reflect with the original dataset as the proportion is adjusted based on sampling

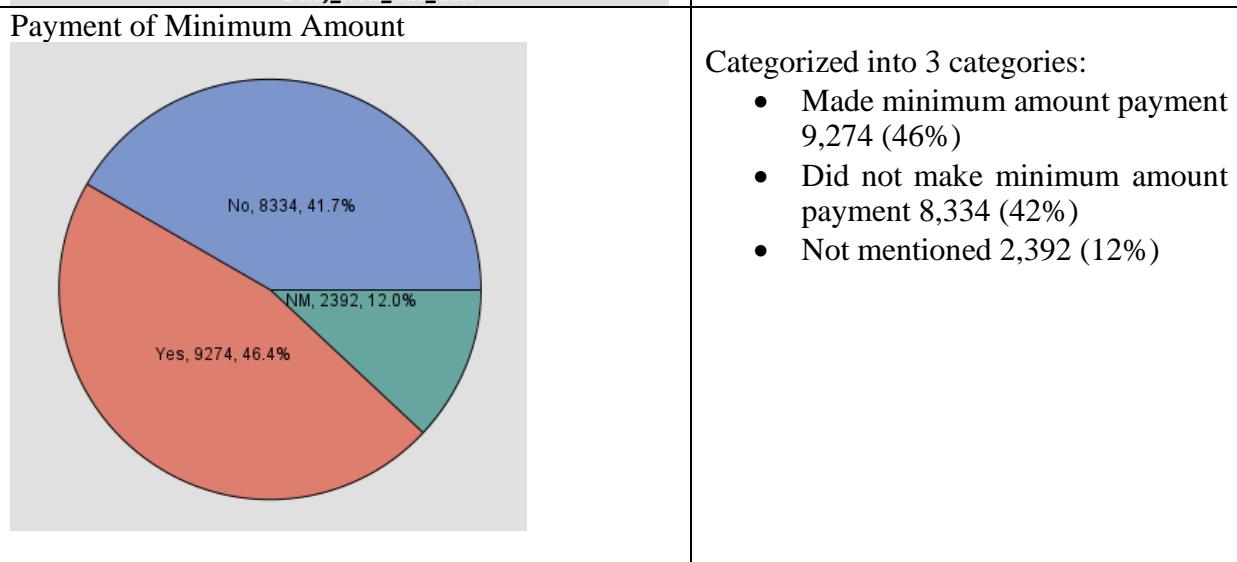

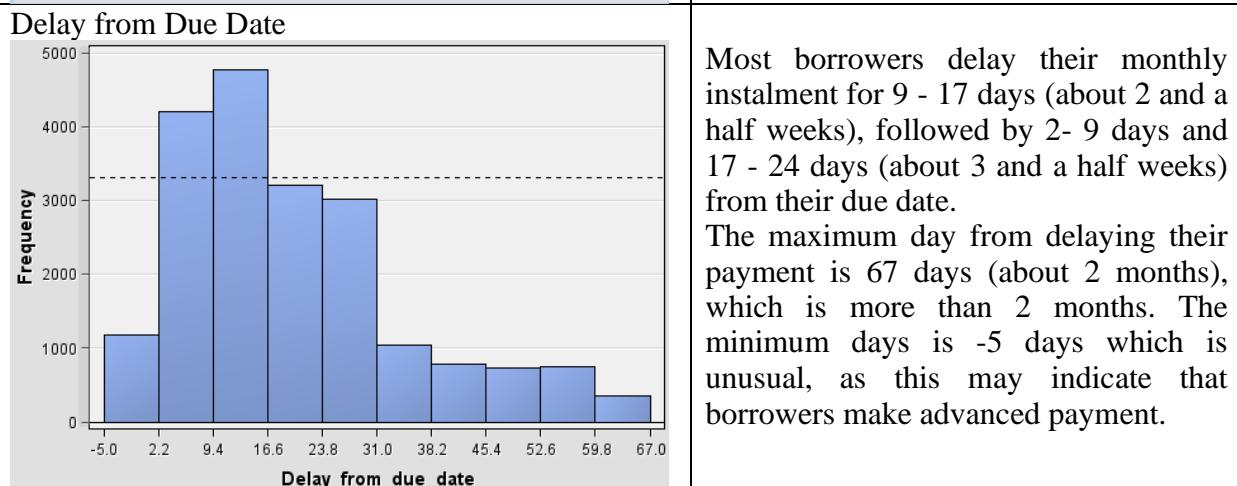

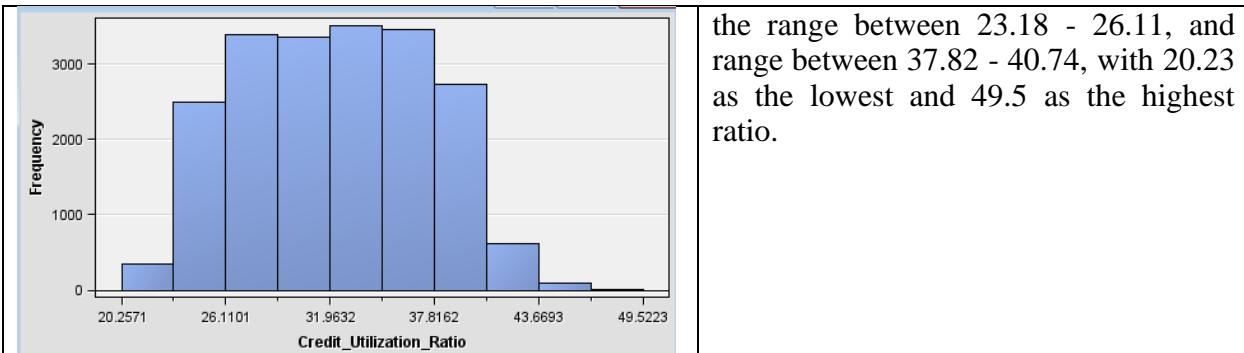

set. The GraphExplore, StatExplore, Multiplot, and Variable Clustering nodes are used by dragging the nodes to the SE diagram and connecting to the Sample node (shown in Appendix).

6.2.1 Univariate Analysis

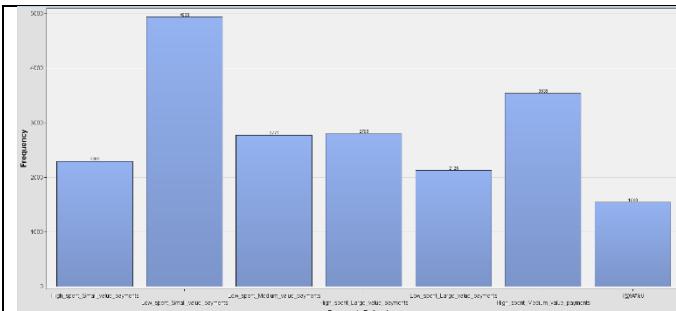

Univariate analysis is conducted by analyzing a single variable in the data using common techniques such as histogram, box plot etc. This analysis aims to describe the data, compare the spread of the variable as well as to find patterns and anomalies in the data.

In Figure 6.2.1 below, pie charts, bar graphs and histograms are presented to describe the patterns of each variable of the dataset.

Variables	Findings															
<p>Credit Score</p> <table border="1"> <thead> <tr> <th>Category</th> <th>Count</th> <th>Percentage</th> </tr> </thead> <tbody> <tr> <td>Good</td> <td>6676</td> <td>33.4%</td> </tr> <tr> <td>Standard</td> <td>6666</td> <td>33.3%</td> </tr> <tr> <td>Poor</td> <td>6658</td> <td>33.3%</td> </tr> </tbody> </table>	Category	Count	Percentage	Good	6676	33.4%	Standard	6666	33.3%	Poor	6658	33.3%	<p>Class target variable which uses stratified sampling and break down into 3 categories with different proportions and percentage:</p> <ul style="list-style-type: none"> • Good – 6,676 (33%) • Standard – 6,666 (34%) • Poor – 6,658 (33%)

<p>Credit Utilization Ratio</p>	<p>Based on credit utilization ratio variable, most borrowers' credit utilization ratio falls between 26.11 - 37.82, followed by</p>															

Payment Behavior

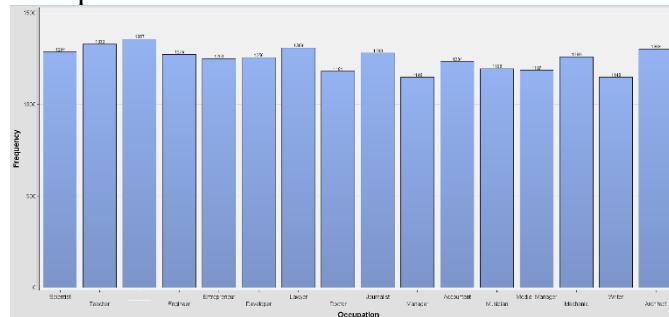

Payment behavior is a breakdown into spending power and value of payments categories. The categories are ranked from highest to lowest frequency as below:

- Low spending with small value payment 4,938 (25%)
- High spending with medium value payment 3,538 (18%)
- High spending with large value payment 2,796 (14%)

There are 1,540 invalid values found in this variable.

Occupation

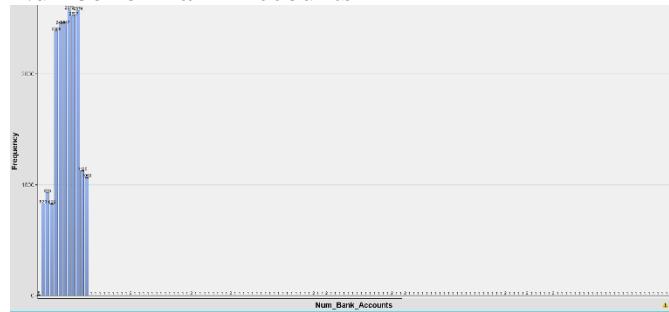

The occupation across the borrowers is fairly distributed, with the occupation types ranked from highest to lowest frequency:

- Teacher 1,330 (7%)
- Lawyer 1,309 (7%)
- Architect 1,303 (7%)

There are unknown values amounting to 1,357 (7%) of the dataset.

Number of Bank Accounts

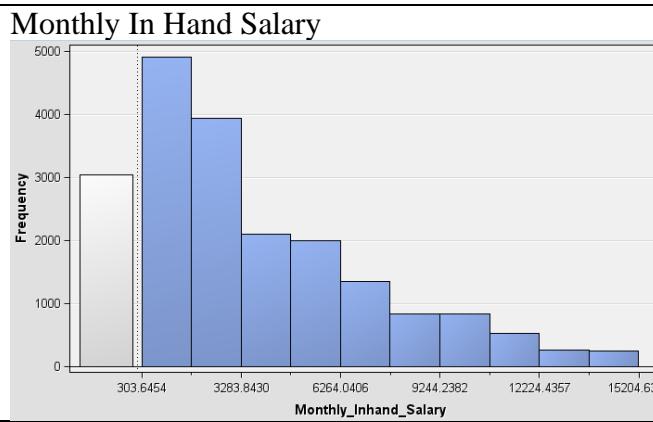

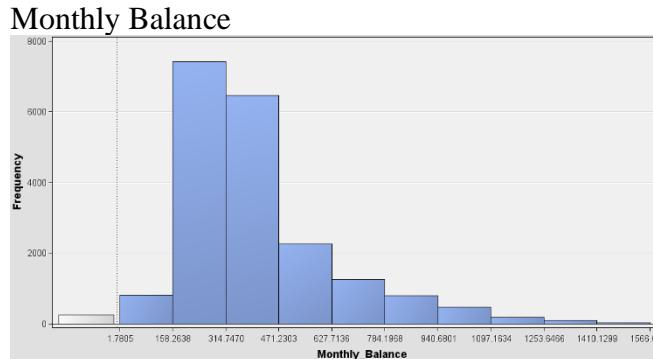

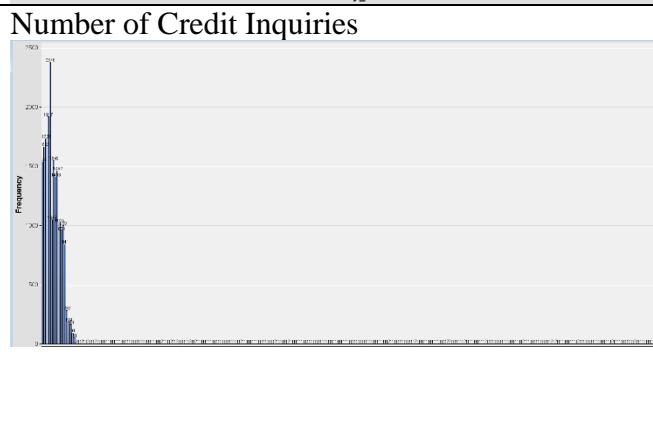

The variable shows that mostly the number of bank accounts a borrower has lies between 1-10 accounts.

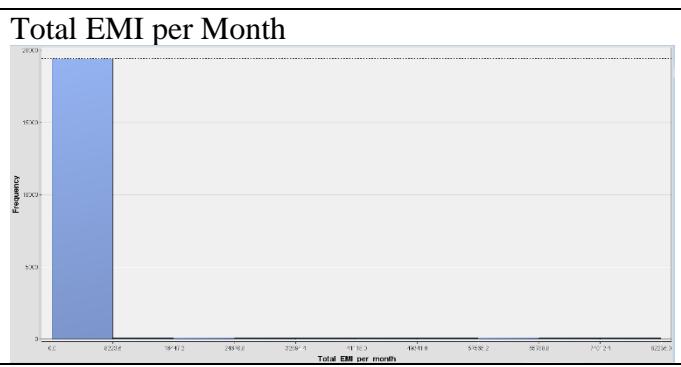

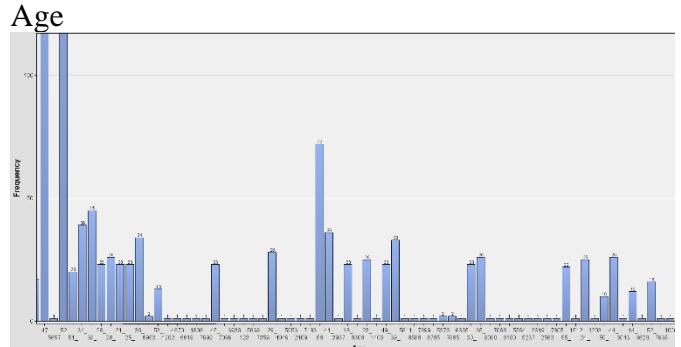

Unusual pattern detected in the variable. Reason being are due to:

- Dirty data is found, which the data type is detected as character, rather than numeric.
- Noisy data is detected with 835 invalid values showing 0 number of accounts, which is unusual as each borrower must have at least 1 bank account to obtain a loan.

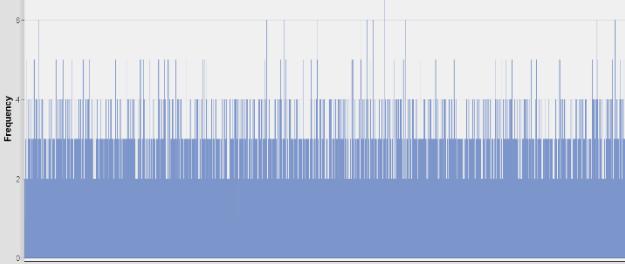

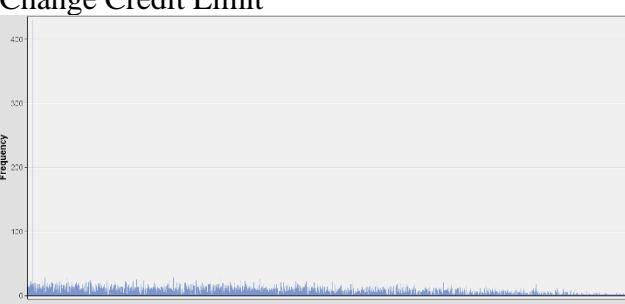

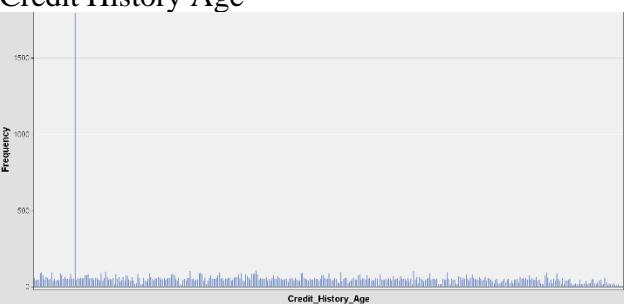

Interest Rate

The variable shows that the interest rate mostly falls between 0-34%, with 8% as

	<p>the most common interest rate for 1,081 borrowers. Unusual pattern detected in the variable. Reason being are due to:</p> <ul style="list-style-type: none"> Noisy data detected with maximum interest rate of 5,775% shown which is abnormal as the maximum value for interest rate should be 100%. 																										
<h3>Monthly In Hand Salary</h3>  <table border="1"> <thead> <tr> <th>Salary Range</th> <th>Frequency</th> </tr> </thead> <tbody> <tr><td>0 - 303</td><td>~3000</td></tr> <tr><td>303 - 6454</td><td>~4900</td></tr> <tr><td>6454 - 8430</td><td>~3900</td></tr> <tr><td>8430 - 10406</td><td>~2100</td></tr> <tr><td>10406 - 12382</td><td>~1300</td></tr> <tr><td>12382 - 14357</td><td>~800</td></tr> <tr><td>14357 - 15333</td><td>~400</td></tr> </tbody> </table>	Salary Range	Frequency	0 - 303	~3000	303 - 6454	~4900	6454 - 8430	~3900	8430 - 10406	~2100	10406 - 12382	~1300	12382 - 14357	~800	14357 - 15333	~400	<ul style="list-style-type: none"> Right-skewed distribution with 4,898 borrowers (24%) having a monthly in hand salary between \$303 and \$1,794, and 3,936 (20%) having salary in between \$1,793 and \$3,286. 3,042 missing values detected in this variable.

	<ul style="list-style-type: none"> • Highly skewed distribution. • 19,397 of the Estimated monthly instalment (EMI) records (97%) lie between \$0 and \$8226. • Outliers detected with a maximum value of \$82,236 EMI.
	<p>Unusual pattern in the data due to dirty data as the data type is detected as character, rather than numeric. Data cleaning is required to reflect the accuracy of the age distribution.</p>
	<p>Unusual pattern in the data due to dirty data as the data type is detected as character, rather than numeric. Data cleaning is required to reflect the accuracy of the amount invested monthly distribution.</p>
	

Annual Income	
---------------	--

 <p>A histogram showing the frequency distribution of Annual_Income. The x-axis is labeled 'Annual_Income' and the y-axis is labeled 'Frequency'. The distribution is highly right-skewed, with a large number of observations clustered at lower income levels and a long tail of high-income outliers.</p>	<p>Unusual pattern in the data due to dirty data as the data type is detected as character, rather than numeric. Data cleaning is required to reflect the accuracy of the annual income distribution.</p>
<h3>Change Credit Limit</h3>  <p>A histogram showing the frequency distribution of Changed_Credit_Limit. The x-axis is labeled 'Changed_Credit_Limit' and the y-axis is labeled 'Frequency'. The distribution is relatively uniform across the range of values, with no clear central tendency.</p>	<p>Unusual pattern in the data due to dirty data as the data type is detected as character, rather than numeric. Data cleaning is required to reflect the accuracy of the change credit limit distribution.</p>
<h3>Credit History Age</h3>  <p>A histogram showing the frequency distribution of Credit_History_Age. The x-axis is labeled 'Credit_History_Age' and the y-axis is labeled 'Frequency'. The distribution is relatively uniform across the range of values, with no clear central tendency.</p>	<p>Unusual pattern in the data due to dirty data as the data type is detected as character, rather than numeric. Data cleaning is required to reflect the accuracy of the credit history age distribution.</p>
<h3>Number of Delayed Payment</h3>  <p>A histogram showing the frequency distribution of Num_of_Delayed_Payment. The x-axis is labeled 'Num_of_Delayed_Payment' and the y-axis is labeled 'Frequency'. The distribution is highly right-skewed, with a large number of observations clustered at lower values and a long tail of high values.</p>	<p>Unusual pattern in the data due to dirty data as the data type is detected as character, rather than numeric. 1,416 records shown as missing values. Data cleaning is required to reflect the accuracy of the number of delayed payment distribution.</p>

Number of Loan	
----------------	--

	<p>Unusual pattern in the data due to dirty data as the data type is detected as character, rather than numeric. 978 is shown as the maximum value of loan, which is unusual and inaccurate as the number of loans is not arranged according to numerical order. Data cleaning is required to reflect the accuracy of the number of loan distribution.</p>
<p>Outstanding Debt</p> 	<p>Unusual pattern in the data due to dirty data as the data type is detected as character, rather than numeric. Data cleaning is required to reflect the accuracy of the outstanding debt distribution.</p>
<p>Type of Loan</p> 	<p>Unusual pattern in the data due to dirty data as the data type is detected as character, rather than numeric. Data cleaning is required to reflect the accuracy of the loan type distribution.</p>

6.2.2 Bivariate Analysis

Unlike univariate analysis, bivariate analysis is a statistical method used to examine the relationship between two variables by analyzing the degree of association or correlation between them and identifying patterns or trends in the data. In this project, we focus on exploring the relationship between two input variables and examining how each continuous input variable is connected to the target variable with scatter plots and bar plots to illustrate these relationships. By conducting this bivariate analysis, valuable insights on how the variables are related can be obtained, thus informed decisions can be made based on the findings.

6.2.2.1 Bivariate Analysis on Input Variables

Identifying relationships between features is crucial in selecting pertinent input variables for a machine learning model, guiding feature engineering efforts, improving model performance, as well as interpreting the analysis results for better decision making.

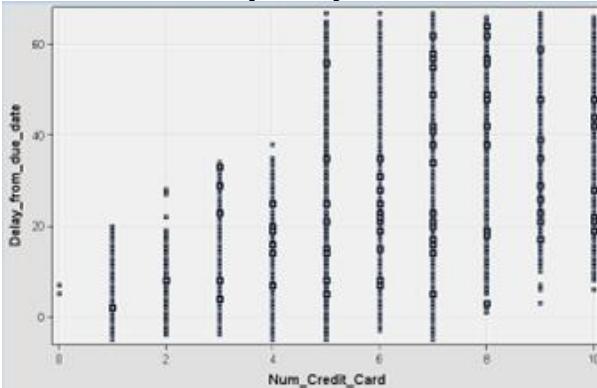

Figure 6.2.2.1 below displays and describes the connection between two input variables in the dataset.

Bivariate Analysis Graphs	Findings
<p>Num Credit Card by Monthly Inhand Salary</p>	<p>Based on the first plot, it is observed that the Num Credit Card variable contains a lot of outliers, and most customers fall in the range of 0 to 10 credit cards.</p> <p>Focusing on customers with credit cards less than or equal to 10, there is a huge drop in the monthly in-hand salary for customers owned more than 7 credit cards.</p>
<p>Num Credit Card by Monthly Balance</p>	<p>It is clearly seen that the monthly balance experienced a huge fall for customers owned more than 7 credit cards, showing a similar trend described in Num Credit Card and Monthly Inhand Salary.</p> <p>This indicates there may be a strong connection between monthly in-hand salary and monthly balance, but more study is needed to assure their relationship.</p>
<p>Monthly Inhand Salary by Monthly Balance</p>	

It is proven that the higher the monthly in-hand salary, the higher the monthly balance of the customer.

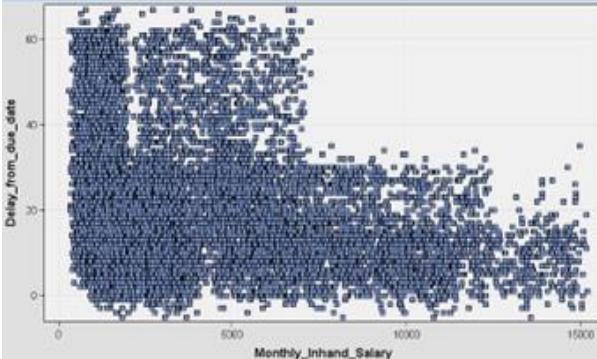

Num Credit Card by Delay from due date

Customers tend to pay their credit card debt later if they have more credit cards. The number of days delayed from the payment due date increases sharply if the customer holds more than 4 credit cards. This is reasonable as taking multiple credit cards can make debt repayments unsustainable.

Since there is some connection between the number of credit cards and delay from due date, and number of credit card and monthly in-hand salary, then it is worth to investigate the relationship between monthly in-hand salary and delay from due date.

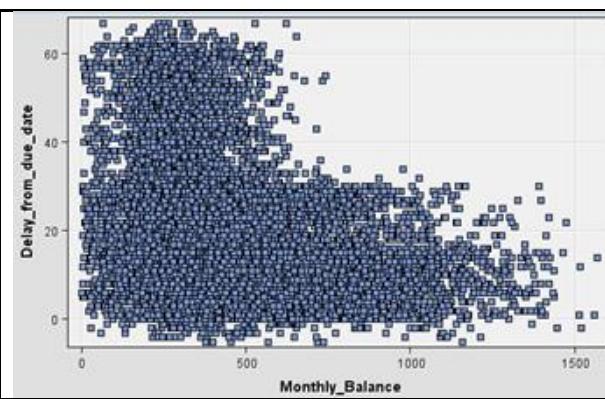

Monthly Inhand Salary by Delay from due date

It is observed that the number of customers with monthly in-hand salary more than 2000 and pay loan later than 40 days from due date is reduced, and all customers with monthly in-hand salary greater than 7000 settled their debt in less than 40 days from due date.

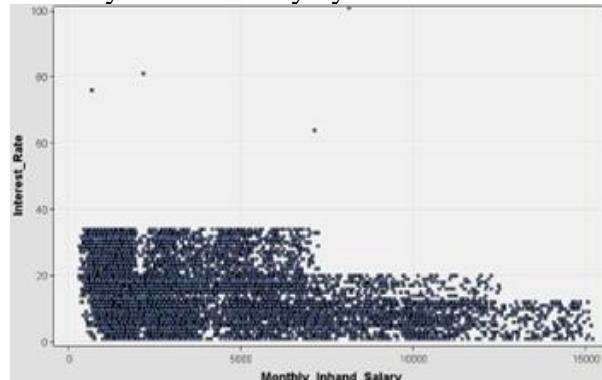

Customers with higher monthly in-hand salary pay their debt earlier, as compared to those with lower monthly in-hand salary.

Monthly Balance by Delay from due date

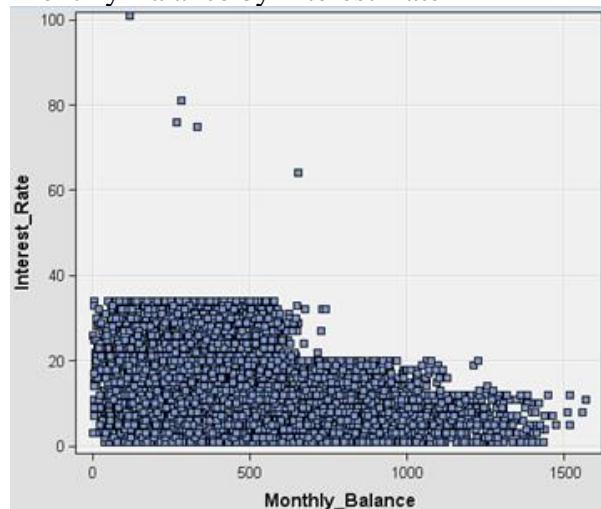

Similar pattern is observed in this plot as compared to the monthly in-hand salary and delay from due date scatter plot. There is also a huge drop in the number of customers who make payment 40 days after the due date if their monthly balance is more than 500.

Monthly Inhand Salary by Interest Rate

Similar patterns are observed in these plots as compared to the monthly in-hand salary and delay from due date scatter plot. The interest rate falls by half for customers with monthly in-hand salary more than 7000 and monthly balance more than 500.

Monthly Balance by Interest Rate

Interest Rate by Delay from due date

	<p>Customers with higher interest rates on their credit cards are suffering from paying their credit card debt as those with credit card interest higher than 20% delayed their payment twice times more than those with credit card interest less than 20%.</p>																																							
<p>Payment of Min Amount by Credit Mix</p> <table border="1"> <thead> <tr> <th>Payment_of_Min_Amount</th> <th>Credit_Mix</th> <th>Frequency</th> </tr> </thead> <tbody> <tr> <td>No</td> <td>Good</td> <td>~7000</td> </tr> <tr> <td>No</td> <td>Standard</td> <td>~1500</td> </tr> <tr> <td>No</td> <td>Bad</td> <td>~1000</td> </tr> <tr> <td>Yes</td> <td>Good</td> <td>~6000</td> </tr> <tr> <td>Yes</td> <td>Standard</td> <td>~2000</td> </tr> <tr> <td>Yes</td> <td>Bad</td> <td>~1000</td> </tr> <tr> <td>NM</td> <td>Good</td> <td>~500</td> </tr> <tr> <td>NM</td> <td>Standard</td> <td>~1000</td> </tr> <tr> <td>NM</td> <td>Bad</td> <td>~500</td> </tr> </tbody> </table>	Payment_of_Min_Amount	Credit_Mix	Frequency	No	Good	~7000	No	Standard	~1500	No	Bad	~1000	Yes	Good	~6000	Yes	Standard	~2000	Yes	Bad	~1000	NM	Good	~500	NM	Standard	~1000	NM	Bad	~500	<p>Most customers who paid only minimum monthly payments on their credit card have standard to low credit mix score while customers who made payment more than required minimum amount or full amount have standard to good score.</p>

6.2.2.2 Bivariate Analysis on Input and Target Variables

Bivariate analysis serves as one of the tools for determining whether there is a correlation between the input features and the target variable. This is vital in a predictive modelling context as the strength of the relationship will significantly impact the accuracy and interpretation of the model. A feature with strong positive or negative correlation to the target variable is treated as a dependable predictor, and thus it is worth to incorporate into the model training stage to boost the accuracy. Conversely, a feature with weak to no correlation is not useful to the predictive model as it will not enhance the model accuracy.

Figure 6.2.2.2 below illustrates and explains the relationship between input variables and target variable.

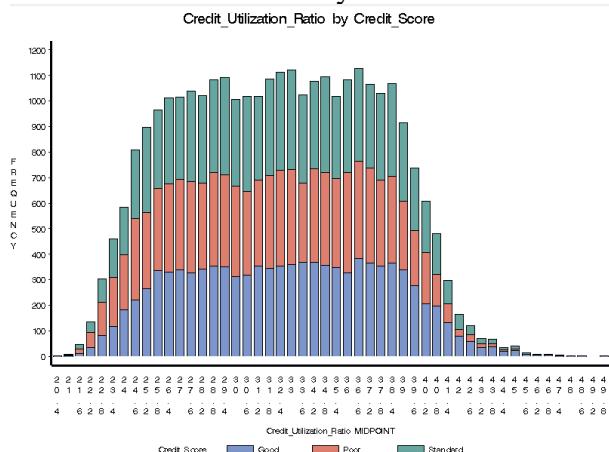

Bivariate Analysis Graphs	Findings
---------------------------	----------

Credit Mix by Credit Score

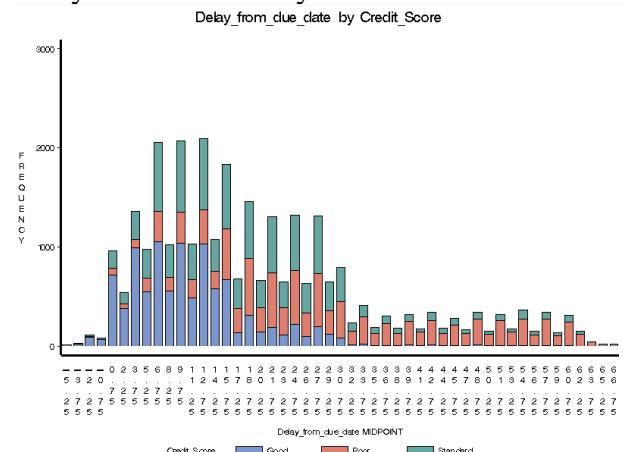

The credit mix is related to credit score as shown in the graph where most customers with good credit mix also obtained good credit score.

Credit Utilization Ratio by Credit Score

The credit utilization ratio shows a normal distribution with almost equal portion of good, standard, and poor credit score at most of the bins.

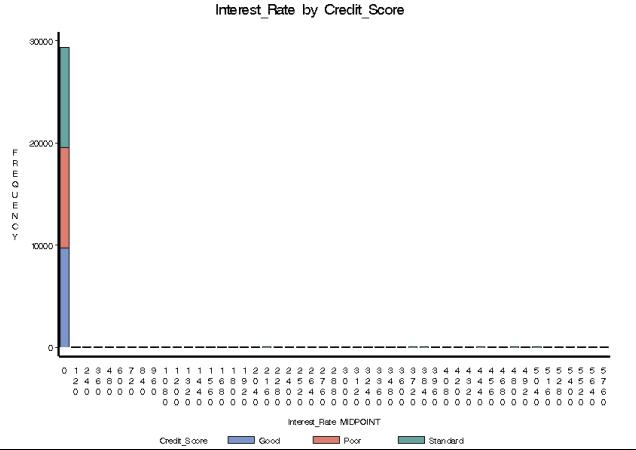

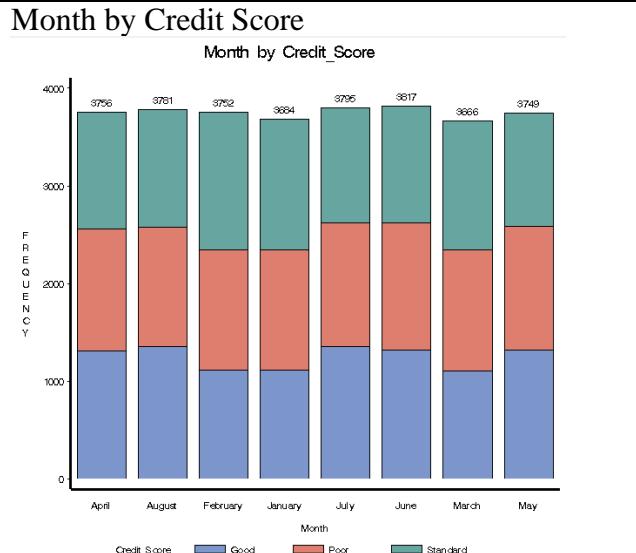

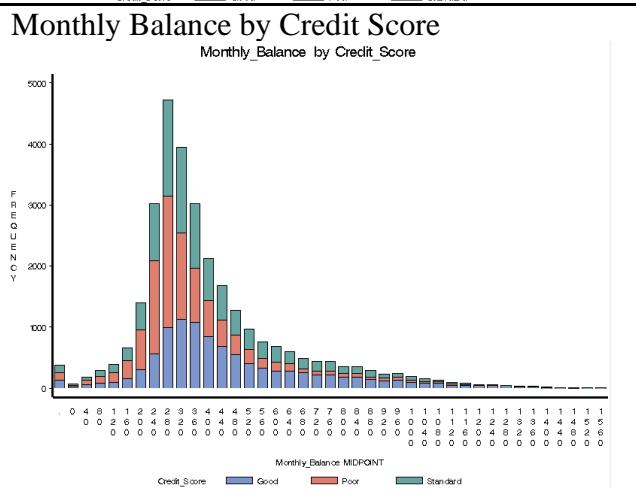

Delay from due date by Credit Score

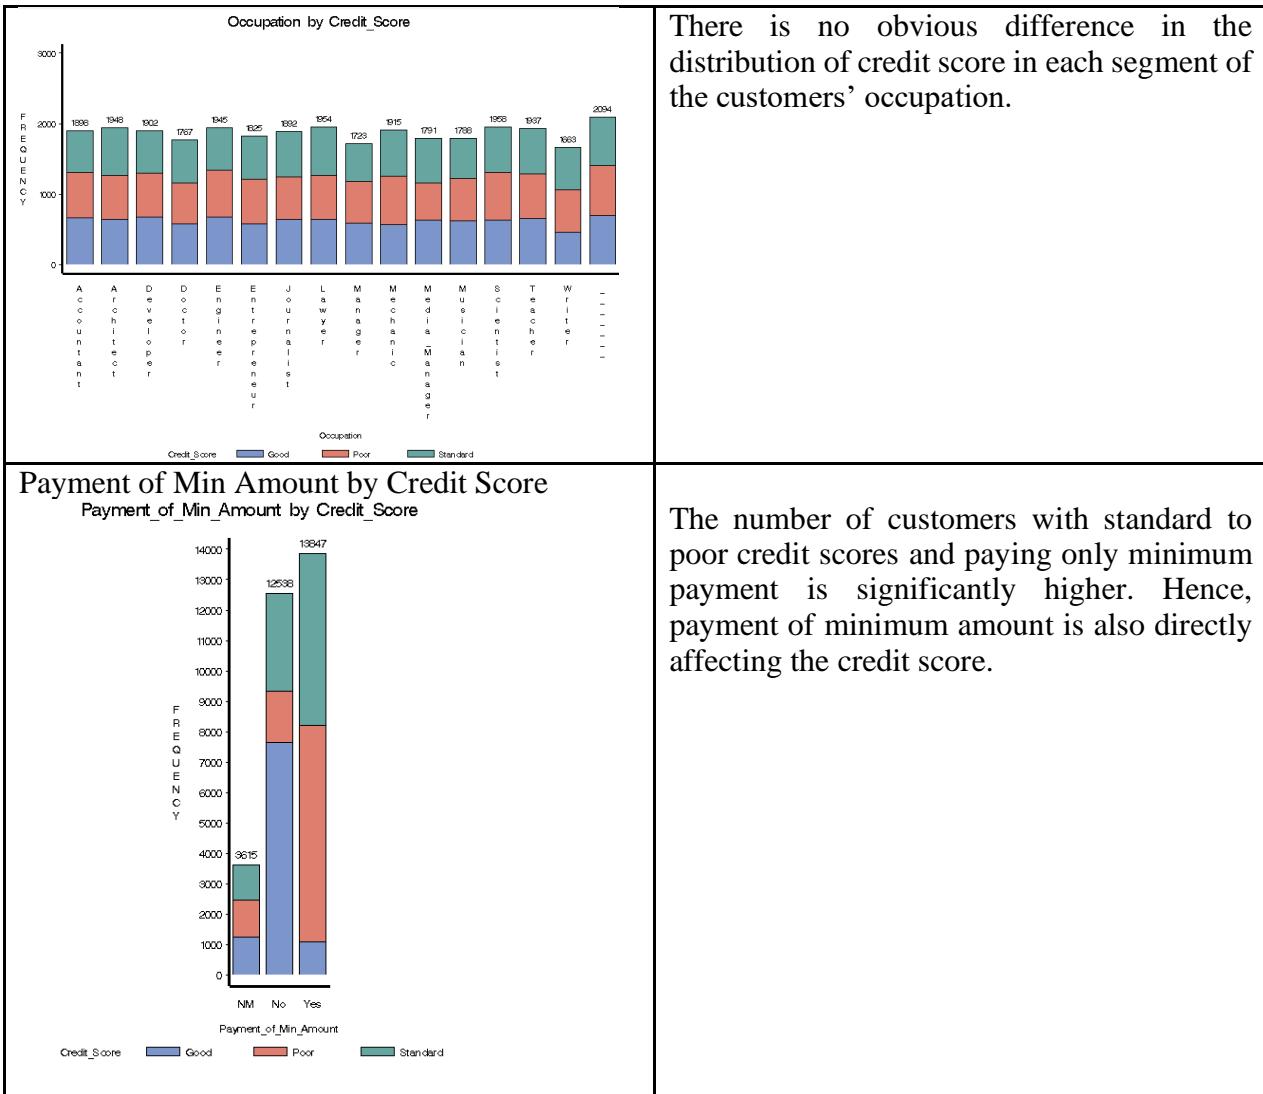

The proportion of customers with standard and good credit score reduced, and the number of customers with poor credit score rose when the number of days delayed from due date increased.

This indicates that customers with good credit scores pay their credit card debt much earlier than those with poor credit score.

Interest Rate by Credit Score

 <p>The bar plot did not show any meaningful results due to outliers in interest rate.</p>

plot illustrates a right-skewed normal distribution with a small spike at monthly balance less than 0. Customers with poor credit scores are relatively high when the monthly balance is closer to mean, but the number of customers drops drastically when the monthly balance gets higher. This shows the connection between monthly balance and credit score although it is not that obvious as compared to other plots.</p>

<h3>Occupation by Credit Score</h3>																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																								

6.2.3 Multivariate Analysis

Multivariate analysis is a statistical method that studies simultaneous effect of more than two independent variables and the relationships among the datasets.

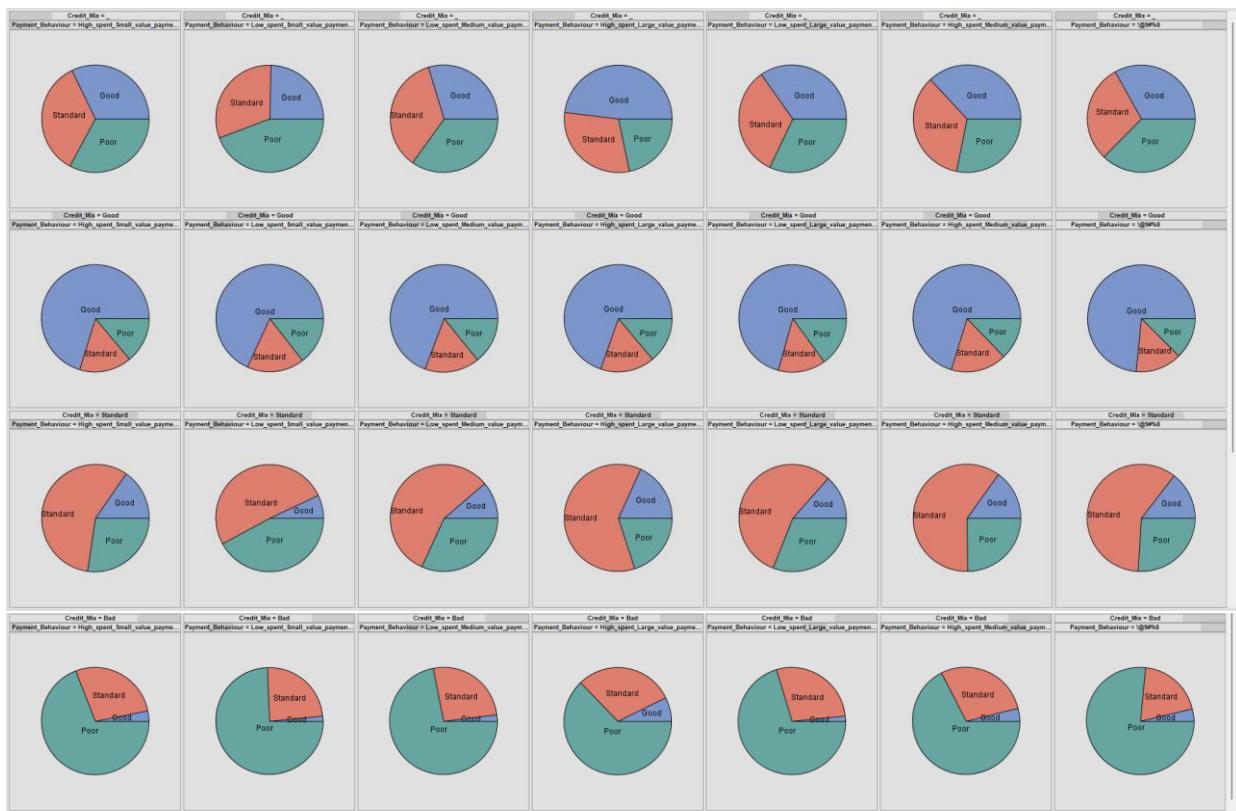

Figure 6.2.3.1 Lattice Pie Charts

The Lattice Bar Charts show how the categories Payment_Behaviour, and Credit_Mix, correlate with Credit_Score. Generally, having a good Credit_Mix gives a good Credit_Score, standard Credit_Mix gives a standard Credit_Score, and poor Credit_Mix gives a poor Credit_Score regardless of the Payment_Behaviour. When the Credit_Mix is undefined, High_spent Payment_Behaviour does not really affect the Credit_Score unless Large_value_payments are made, which increases the likelihood of a good Credit_Score. Low_spent Payment Behaviour also does not affect Credit_Score unless Small_value_payments are made, which results in poor Credit_Score.

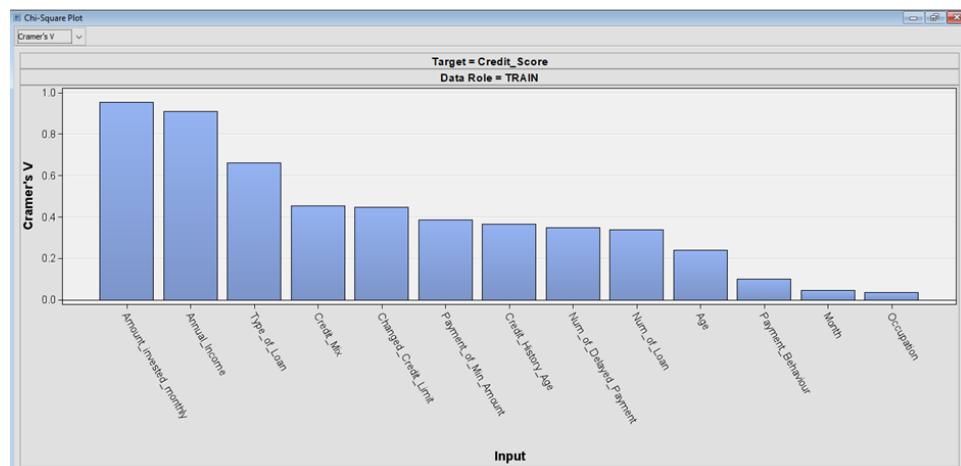

Figure 6.2.3.2 Cramer's V Statistics with respect to the Target Variable

Figure 6.2.3.2 shows Cramer's V measure in which the 0 value indicates no association whereas the 1 indicates perfect association between the two variables. The threshold value is set to 0.1. Thus, Amount invested monthly, Annual Income, Type of Loan, Credit Mix, Changed Credit Limit, Payment of Min Amount, Credit History Age, Num of Delayed Payment, Num of Loan, Age, and Payment Behaviour show association with the target variable which is the Credit Score. Meanwhile, Month and Occupation show nearly no association with Credit Score.

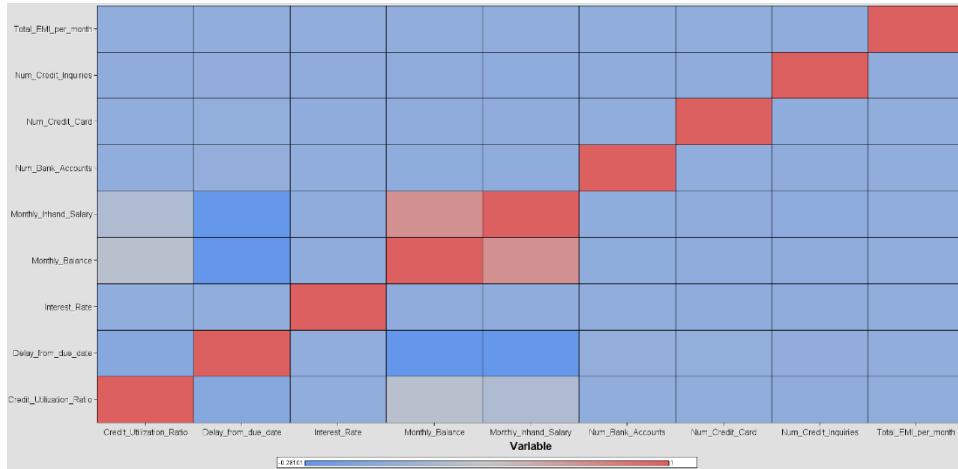

Figure 6.2.3.3 Correlation Matrix

Table 6.3.2.1 Correlation Table

Variable 1	Variable 2	Correlation
Credit_Utilization_Ratio	Credit_Utilization_Ratio	1.000
Credit_Utilization_Ratio	Delay_from_due_date	-0.055
Credit_Utilization_Ratio	Interest_Rate	0.001

The correlation matrix and table can be used to determine the variables to be dropped based on the correlation coefficients. The correlation matrix takes the outliers into consideration when calculating the correlation. The closer the number is to 1 or -1, the stronger the correlation. The closest positive correlation value obtained was 0.7 from Monthly In-hand Salary and Monthly Balance. However, since none of the values were in the range of |0.9| to |1|, none of the variables were dropped.

Figure 6.2.3.6 Variable Selection Table with Best Variable

Figure 6.2.3.4 and Figure 6.2.3.5 depict the variable clustering of the dataset prior to any data cleaning and transformation. There were three clusters made due to each cluster satisfies the stopping criteria specified in the Variation Proportion property. The first cluster is made of Credit_Utilization_Ratio, Monthly_Balance, Delay_from_due_date, Monthly_Inhand_Salary. The second cluster consists of Num_Bank_Accounts, Num_Credit_Inquiries, and Total_EMI_per_month. The last cluster has Num_Credit_Card and Interest_Rate. Monthly_Balance, Num_Credit_Inquiries, and Interest_Rate were the best variable in each cluster with the lowest $1-R^2$ Ratio.

6.2.4 Interesting Visualization

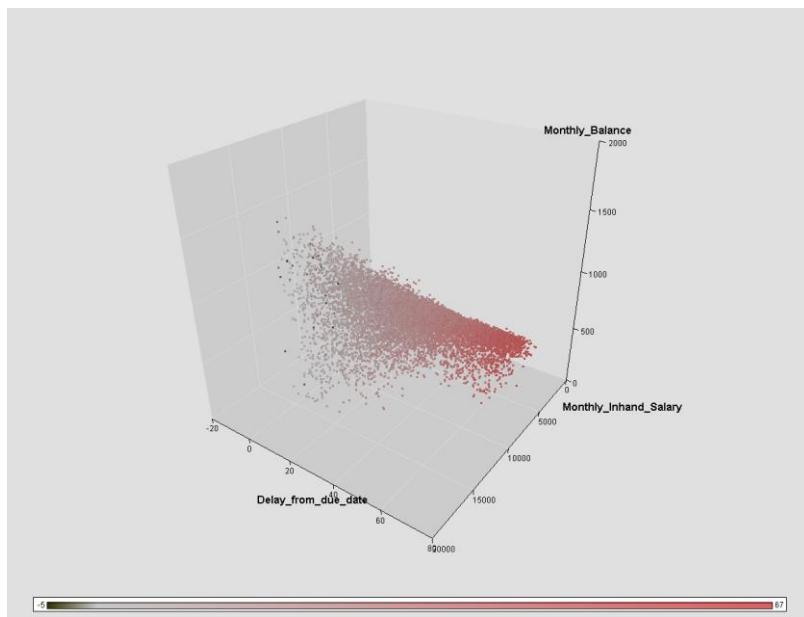

Figure 6.2.4.1 3-dimensional Scatter Plot

The Scatter plot depicts the relationship between Monthly_Inhand_Salary (x-axis), Delay_from_due_date (y-axis, colour), and Monthly_Balance (z-axis). From the plot it can be seen that Monthly_Inhand_Salary and Monthly_Balance increase proportionally. As for Delay_from_due_date, it decreases as the Monthly_Inhand_Salary and Monthly_Balance increase.

7 SEMMA: Modify

In the Modify phase, the dataset is first pre-modified via base SAS using SAS Studio, which is a programming language for data access, data transformation, analysis, and reporting. The dataset is then further modified in SAS Enterprise Miner using Modify nodes, such as Impute, Drop, Transform, Replacement nodes etc. After modifying the dataset, each of the variables is explored and the results before and after transformation are compared.

7.1 Pre-modifying Dataset using Base SAS

Base SAS code is used to address the variables level misclassification issues and perform some data cleaning. The following demonstrates the code and describes all the data cleaning steps involved in detail.

1. A library named "cleaning" is created and the dataset is copied to the library for data cleaning purposes. (Figure 12.4.1)
2. A SAS Macro is defined to remove special characters except dot and comma, in each of the character variables in the dataset. (Figures 12.4.2 - 12.4.3)
3. A new unique id column named "id_new" is constructed to overcome the duplication of ID in the dataset. (Figure 12.4.4)
4. The levels of the character variables such as Age, Annual Income, Num of Loan, Num of Delayed Payment, Changed Credit Limit, Outstanding Debt and Amount invested monthly

are finally ready for reclassification. These variables are also rounded to 2 decimal places after converting from character to numeric. (Figure 12.4.5)

5. The Credit History Age variable is transformed into Credit History Year and Credit History Month, then into new Credit History Age variable in year format. For instance, 22 years 10 months is transformed into 22 Credit History Year and 10 Credit History Month, then into 22.83 Credit History Age (year). (Figure 12.4.6)
6. The Type of Loan variable, which contains a bunch of loans with commas in between, is extracted and transformed by splitting the loan by comma, then transposing from column into rows. (Figure 12.4.7)
7. After transposed, the distinct type of loan is obtained, and the dirty data in the type of loan column is cleaned to ensure that the data is consistent, accurate and reliable. (Figure 12.4.8)
8. New variables (auto_loan_f, creditbuilder_loan_f, debt_con_loan_f, home_equi_loan_f, mg_loan_f, not_spec_loan_f, payday_loan_f, personal_loan_f, student_loan_f) are constructed to indicate whether each customer holds a specific loan product. For example, if the customer holds an auto loan, then the auto_loan_f will be tagged as Y, otherwise N. (Figure 12.4.9)
9. These new variables are then merged into the main dataset (the dataset after transformed the Credit History Age at point 5) using the id_new column. (Figure 12.4.10)
10. The Month variables are transformed from character to numeric to ease the exploratory data analysis process later. (Figure 12.4.11)
11. The newly created and transformed variables are renamed accordingly. (Figure 12.4.12)
12. The modified dataset is saved as "em_save_train_modified" in the library which was created in the previous phase to store the data source for Credit Classification Score project. (Figure 12.4.13)

7.2 Modifying Dataset using SAS Enterprise Miner

A new data source is created for the modified dataset named "em_save_train_modified" to further perform data pre-processing process in SAS Enterprise Miner. The roles and levels of the variables in the dataset are reclassified appropriately as shown in Figure 7.2.1, whereas the metadata of the new variables created are described in Table 7.2.1. 1.

As observed in Figure 7.2.1, there are 34 variables in total, which are 1 nominal variable with ID role, 5 nominal variables with Input role, 17 interval variables with Input role, 1 ordinal variable with Input role, 9 binary variables with input role, and 1 binary variable as target role in the dataset.

Name	Role	Level
Age	Input	Interval
Amount_invested_monthly	Input	Interval
Annual_Income	Input	Interval
Changed_Credit_Limit	Input	Interval
Credit_History_Age	Input	Interval
Credit_Mix	Input	Ordinal
Credit_Score	Target	Binary
Credit_Utilization_Ratio	Input	Interval
Customer_ID	Input	Nominal
Delay_from_due_date	Input	Interval

Month	Input	Nominal
Monthly_Balance	Input	Interval
Monthly_Inhand_Salary	Input	Interval
Num_Bank_Accounts	Input	Interval
Num_Credit_Card	Input	Interval
Num_Credit_Inquiries	Input	Interval
Num_of_Delayed_Payment	Input	Interval
Num_of_Loan	Input	Interval
Occupation	Input	Nominal
Outstanding_Debt	Input	Interval
Payment_Behaviour	Input	Nominal
Payment_of_Min_Amount	Input	Nominal
Total_EMI_per_month	Input	Interval
auto_loan_f	Input	Binary
creditbuilder_loan_f	Input	Binary
debt_con_loan_f	Input	Binary
home_equi_loan_f	Input	Binary
id	ID	Nominal
mg_loan_f	Input	Binary
not_spec_loan_f	Input	Binary
payday_loan_f	Input	Binary
personal_loan_f	Input	Binary
student_loan_f	Input	Binary

Figure 7.2.1: The roles and levels of the variables

Column	Description
auto_loan_f	Represents whether the customer holding auto loan
creditbuilder_loan_f	Represents whether the customer holding credit-builder loan
debt_con_loan_f	Represents whether the customer holding debt consolidation loan
home_equi_loan_f	Represents whether the customer holding home equity loan
mg_loan_f	Represents whether the customer holding mortgage loan
not_spec_loan_f	Represents whether the customer holding non-specified loan
payday_loan_f	Represents whether the customer holding payday loan
personal_loan_f	Represents whether the customer holding personal loan
student_loan_f	Represents whether the customer holding student loan

Table 7.2.1: New columns metadata

After creating the data source, the dataset is dragged to the diagram and ready for data pre-processing. The steps involved in Modify stage are discussed in detail as follows, along with the screenshots of how the steps performed in SAS Enterprise Miner in brackets after each step.

1. The values in class variables are replaced with their correct and default values using the Replacement node under the Modify tab as shown in Figures 7.2.2 and 7.2.3 (Figures 12.5.1 - 12.5.8).

Variable	Formatted Value	Replacement Value	Frequency Count	Type	Character Unformatted Value	Numeric Value

Figure 7.2.7: Imputation Summary

5. The "Standard" and "Poor" classes in the target variable "REP_Credit_Score" are grouped together into "Standard to Poor" using the Replacement node as shown in Figure 7.2.8. This is to increase the performance of the machine learning model in classifying customers' credit score. (Figure 12.5.20)

Variable	Formatted Value	Replacement Value	Frequency Count	Type	Character Unformatted Value	Numeric Value
REP_Credit_Score	Good		10000C	Good	.	
REP_Credit_Score	Poor	Standard to Poor	10000C	Poor	.	
REP_Credit_Score	Standard	Standard to Poor	10000C	Standard	.	
REP_Credit_Score	UNKNOWN_	DEFAULT_	C		.	

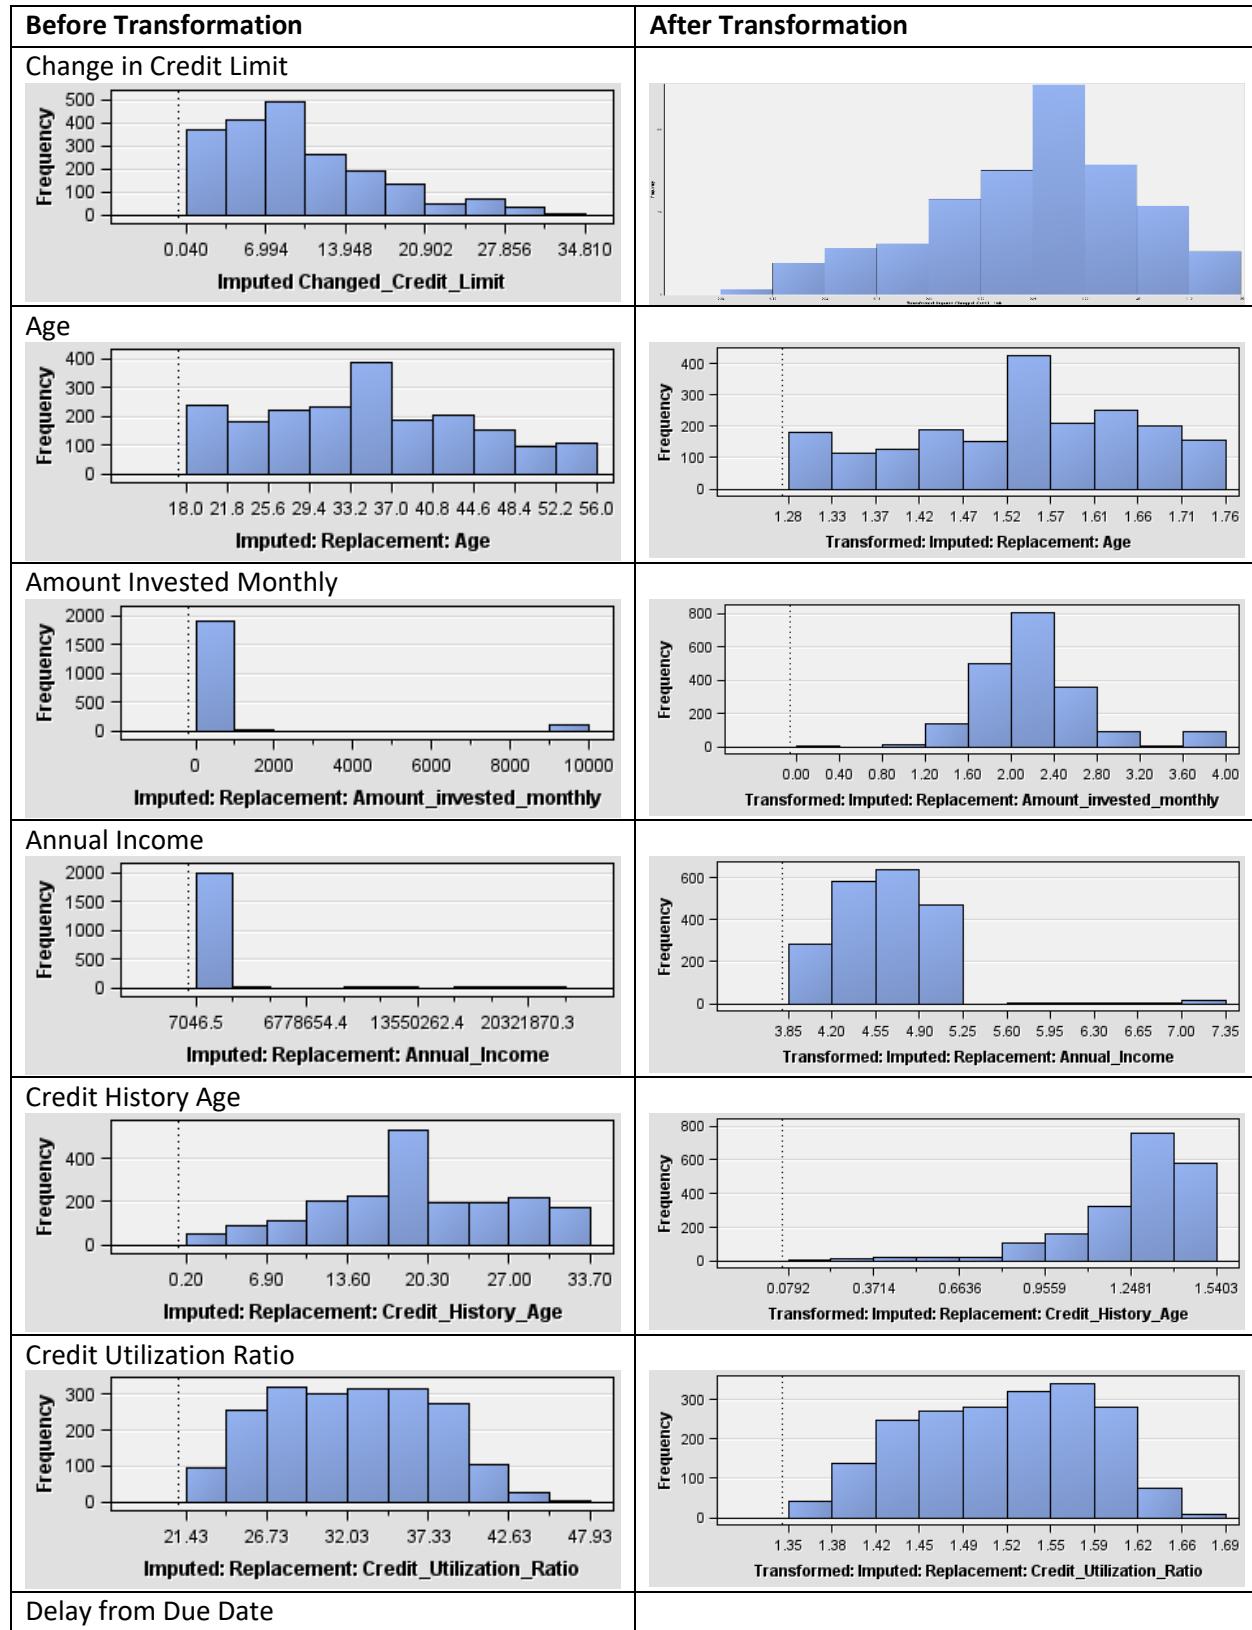

Figure 7.2.8: Recategorizing target variable

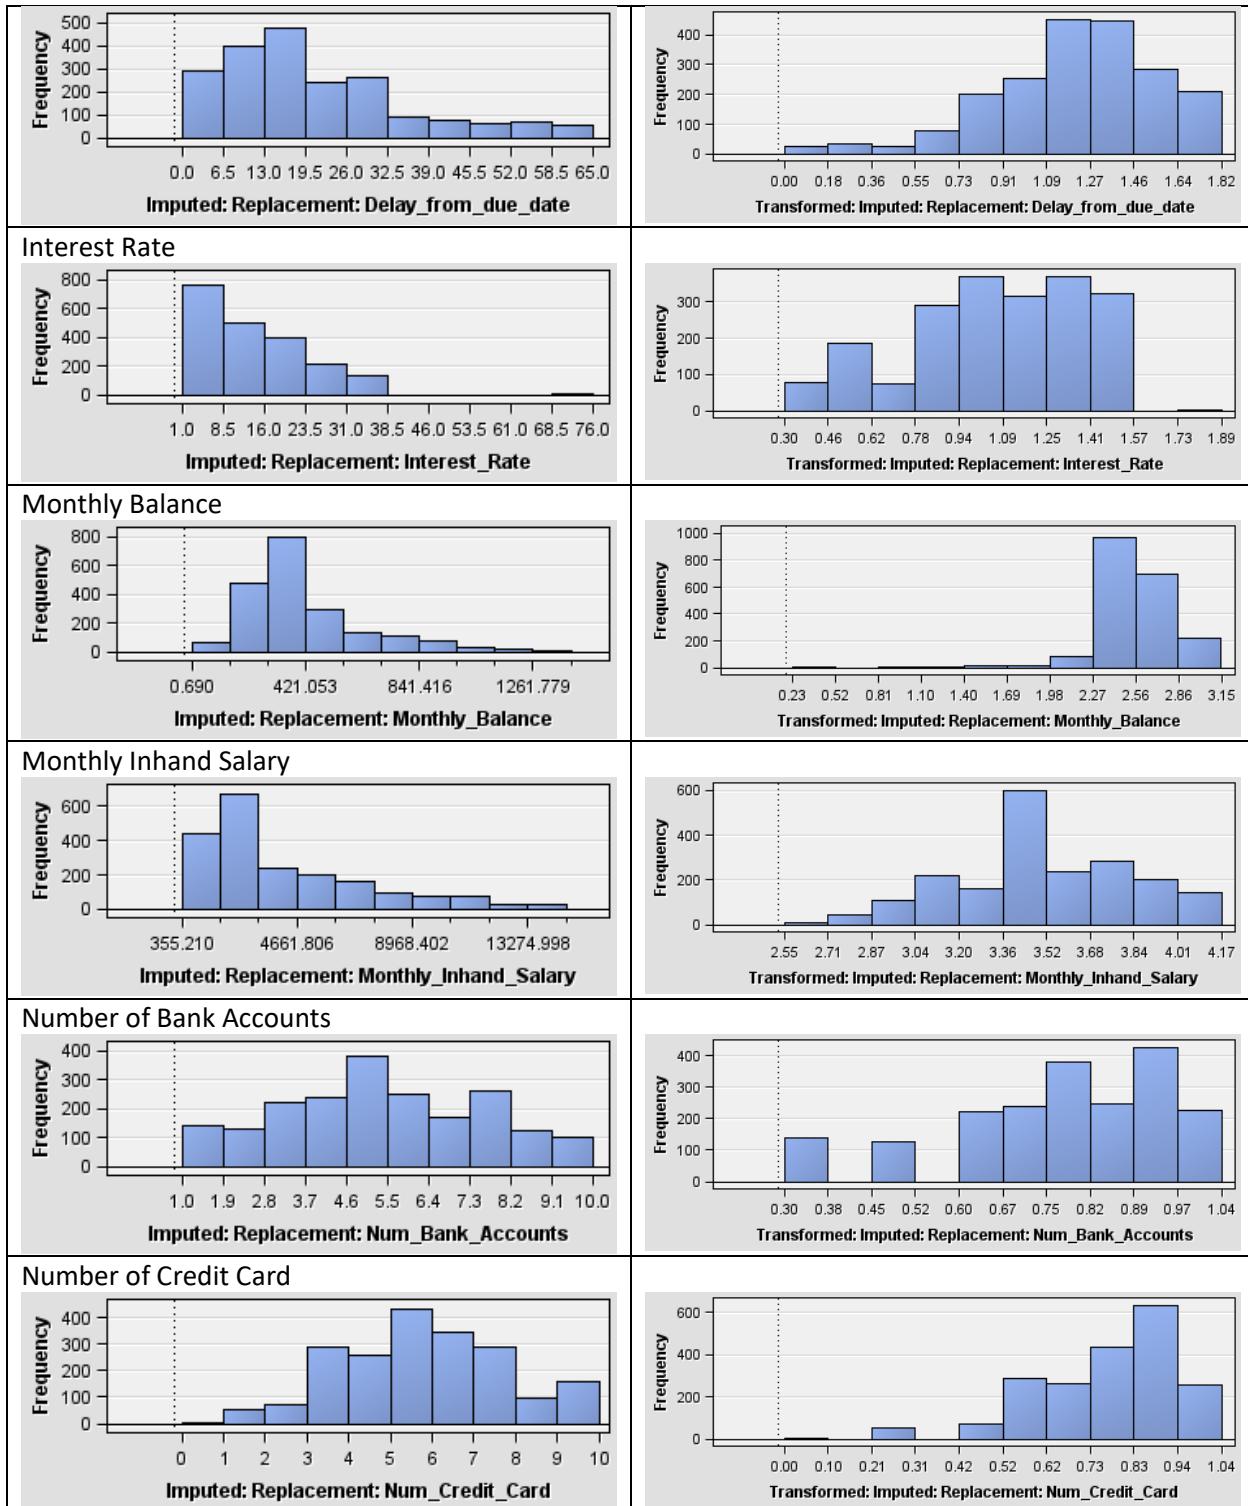

6. The interval variables are normalized using the log 10 transformation in the Transform node as shown in Figure 7.2.9 to transform all features into the same scale. (Figures 12.5.21 - 12.5.24)

7.3 Data Exploration on Cleaned Dataset

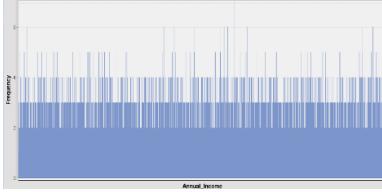

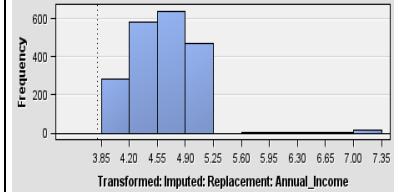

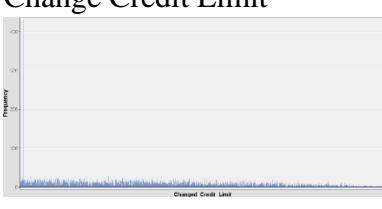

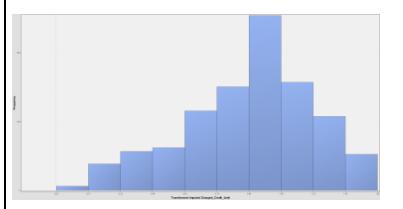

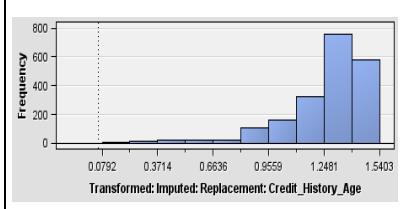

After data cleaning, each of the variables is explored as showcased in Figure 5.3 below.

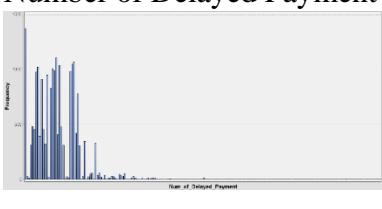

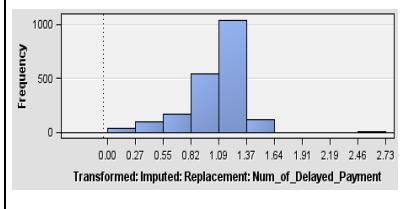

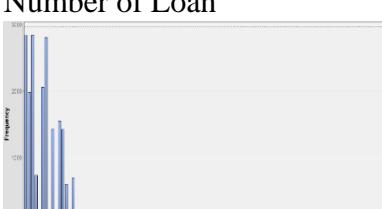

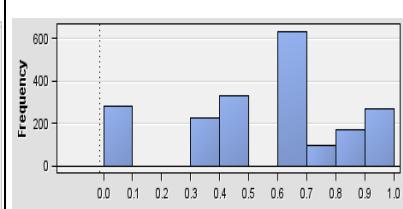

Variables - Before Modify	After Modify	Explanation
Credit Score 		The labels of target variable have combined 'standard' and 'poor' to form a new label, named 'Standard to Poor'. This provides a higher accuracy when predicting the outcome based on the independent class variables.
Credit Mix 		Credit Mix variable was imputed with Count value, resulting in no Missing value in the dataset.
Credit Utilization Ratio 		Normalization using log10 transformation is applied to Credit Utilization Ratio variable to scale down the dataset.
Delay from Due Date 		Normalization using log10 transformation is applied to Delay from Due Date variable to scale down the dataset.
Payment of Minimum Amount 		Payment of Minimum Amount is imputed with Count value, leaving no missing values in the dataset.
Payment Behavior 		Payment behavior with invalid values was imputed with Count value, i.e. Low Spent Small Value Payment, eliminating those invalid values.

<h3>Occupation</h3> 	 <p>Unknown values from occupation were imputed with Count value, i.e. Scientist, eliminating those unknown values.</p>
<h3>Number of Bank Accounts</h3> 	 <p>Dirty and noisy data are cleaned up by formatting character values into numeric, imputing based on median value and normalizing using log 10 transformation.</p>
<h3>Interest Rate</h3> 	 <p>Dirty and noisy data are cleaned up by setting replacement upper limit of 100% using missing as replace method, followed by imputing data using median value and lastly to normalize data using log 10 transformation approach.</p>
<h3>Monthly In Hand Salary</h3> 	 <p>Missing values are imputed using median value, thus showing no missing value after the imputation. Data is normalized to form a smooth bell-curved shape distribution.</p>
<h3>Monthly Balance</h3> 	 <p>Missing value found in monthly balance is imputed based on median value and normalized using log 10 transformation.</p>
<h3>Number of Credit Inquiries</h3> 	 <p>Missing value found in number of credit inquiries is imputed based on median value and normalized using log 10 transformation.</p>
<h3>Number of Credit Cards</h3>	

		<p>Outliers found in number of credit cards were removed by setting replacement upper limit value of 15 with missing replace method. It is then imputed using median value and normalized using log 10 transformation.</p>
Total EMI per Month 		<p>Total EMI was set with replacement lower limit value of 0 with missing replace method. It is imputed using median value, followed by normalisation.</p>

Age 		<p>Dirty data is formatted from character to numeric value. It is then set with replacement lower limit of 18 and upper limit of 75, that is the age limit to apply for loans. The data is then imputed using median value and is normalized.</p>
Amount Invested Monthly 		<p>Dirty data is formatted from character to numeric value. It is then set with replacement lower limit of 0 as amount cannot be less than 0. The data is then imputed using median value and is normalized.</p>
Annual Income		<p>Dirty data is formatted from character to numeric value. Annual income is then set with replacement lower limit of 0 as</p>

		<p>amount cannot be less than 0. The data is then imputed using median value and is normalized.</p>
<h3>Change Credit Limit</h3> 		<p>Dirty data is formatted from character to numeric value. The variable is then imputed using median value and is normalized, forming a bell-curve shape distribution.</p>
<h3>Credit History Age</h3> 		<p>Dirty data is formatted from character to numeric value. It is then set with a replacement lower limit of 0. The data is then imputed using median value and is normalized, forming a left-skewed distribution.</p>

<h3>Number of Delayed Payment</h3> 		<p>Dirty data is formatted from character to numeric value. It is then set with replacement lower limit of 0 and upper limit of 700 as data beyond 700 is deemed as outliers. The data is then imputed using median value and is normalized.</p>
<h3>Number of Loan</h3> 		<p>Dirty data is formatted from character to numeric value. It is then set with a replacement lower limit of 0 and upper limit of 15. The data is then imputed using median value and is normalized.</p>
<h3>Outstanding Debt</h3>		<p>Dirty data is formatted from character to numeric value. It is then set with replacement lower limit of 0 as amount cannot be less</p>

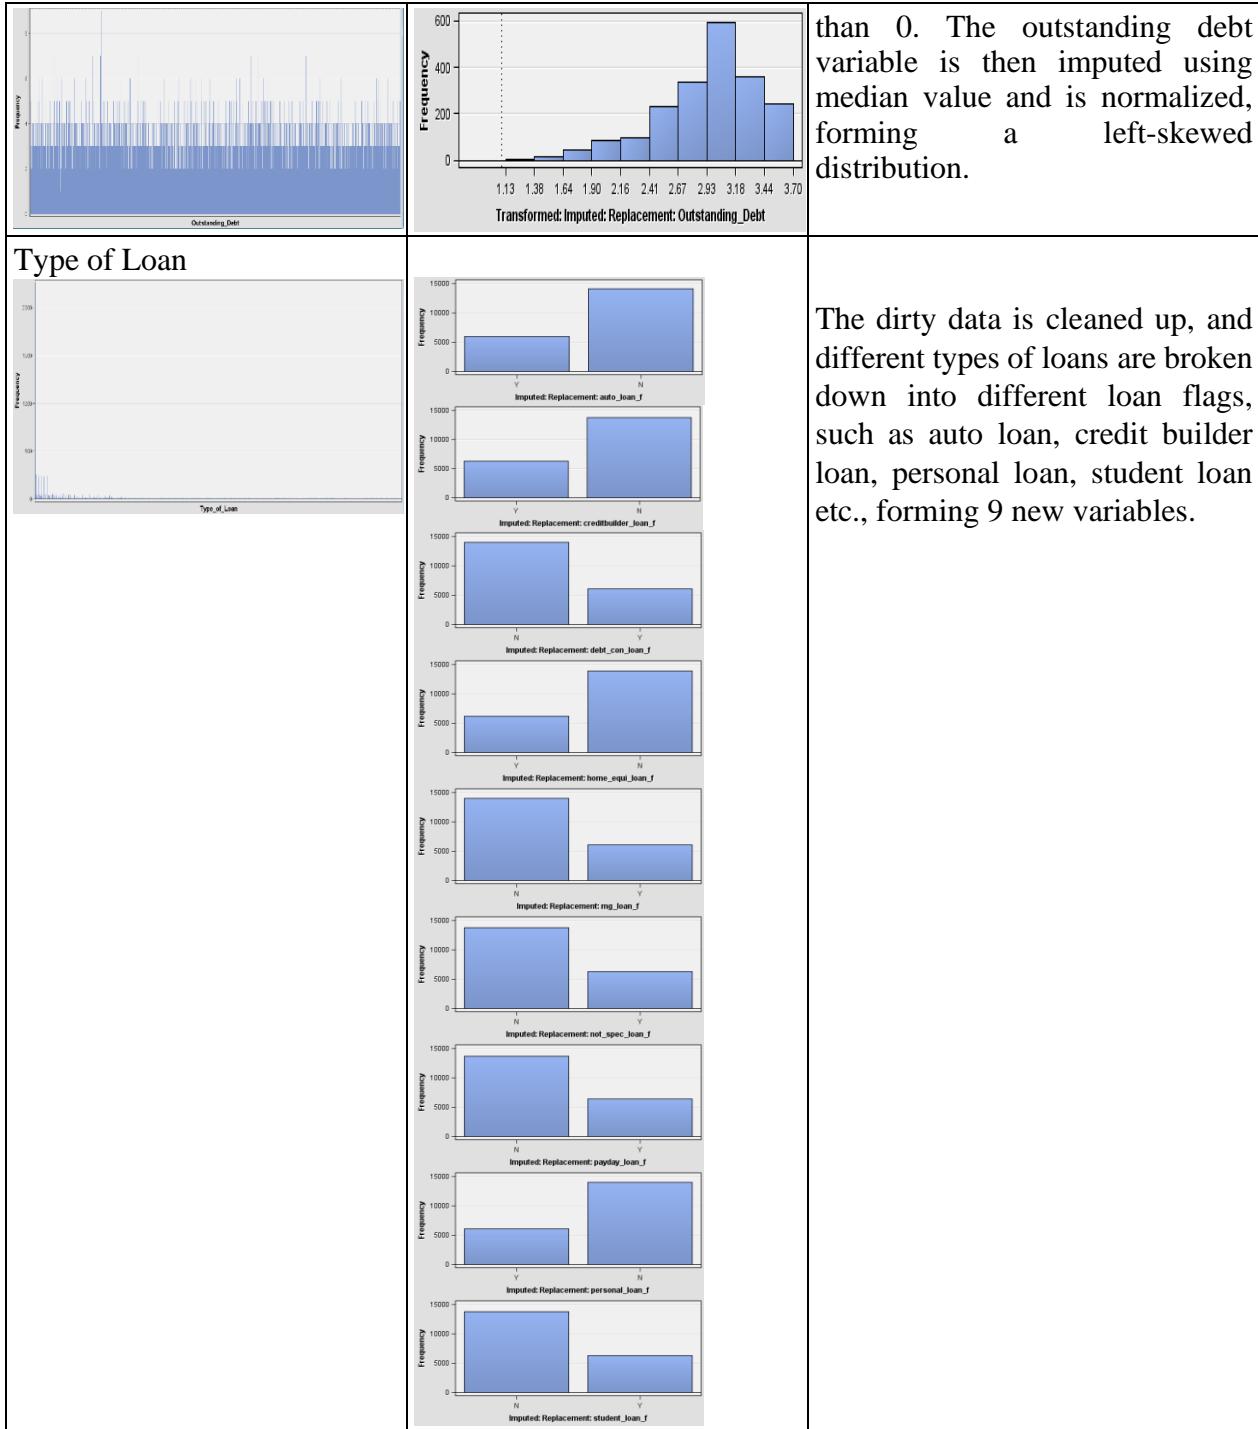

Figure 5.3: Comparison of each variable (before VS after data cleaning)

The relationship between the input variables is explored through correlation matrix under Figure 5.4. It can be seen that annual income and monthly inhand salary has a relative high positive correlation of 0.76, followed by number of loan and total EMI per month, which is 0.59. Delay from due date and number of bank accounts has a positive correlation of 0.49. From the negative correlation view, interest rate and credit history age correlation value is -0.48, followed by number

of loan and credit history age with correlation value of -0.46. Full correlation matrix table as shown in Appendix (Figure 12.5.27)

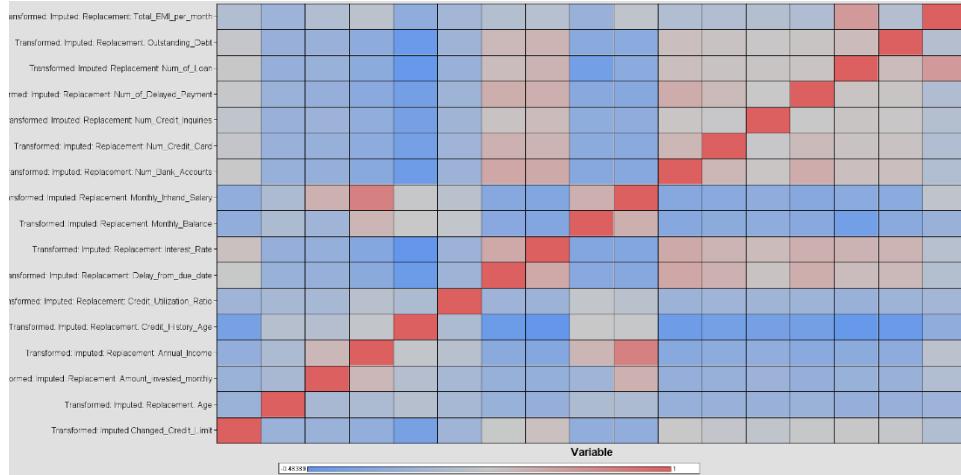

Figure 5.4 Correlation Matrix

Looking from the chi-square bar plots in Figure 5.5, Credit Mix and Payment of Minimum Amount variables show a strong significant association, which might have a potentially meaningful relationship with the Credit Score target variable. Meanwhile, Occupation and Month shows a weaker association between the variables.

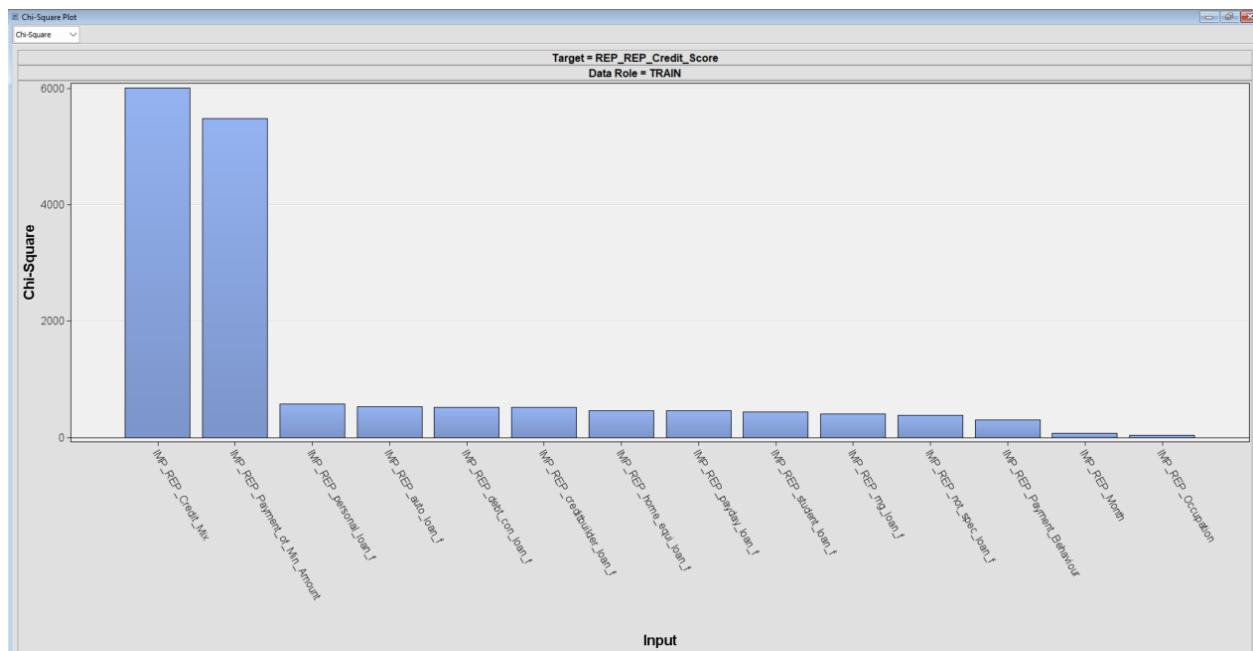

Figure 5.5 Chi-Square Bar Plots between input variables VS target variable

7.4 Data Partitioning

The data partition node was used to split the dataset into training and validation sets at a split ratio of 50:50 as shown in Figure 7.4.1, along with the results in Figure 7.4.2. (Figures 12.6.1 - 12.6.3 show the steps to partition the data.)

8 SEMMA: Model

The training dataset consists of 50% of the data used for the model building. The models used in this project to classify the credit score are the Decision Tree (DT), Logistic Regression (LR), Gradient Boosting (GB), and Least-Angle Regression (LARS).

8.1 Decision Tree Model

A supervised learning technique which is preferred to solve classification problems is known as the Decision Tree (DT). It is a tree-like structure with root nodes, interval nodes, leaf nodes and branches. Internal node is the representation of the features, the branch is the representation of the decision rules, and the leaf node is the representation of the outcomes. The Decision Tree usually mimics the human thinking ability to make decisions, hence it is easy to understand.

The Decision Tree built using our dataset is shown in Figure 8.1.1 below.

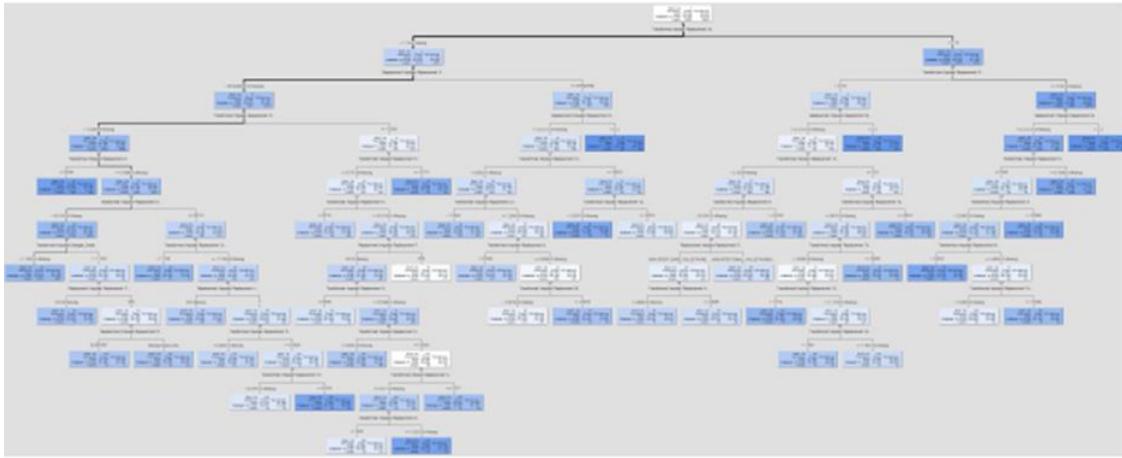

Figure 8.1.1: Decision Tree

Some interesting points while developing the Decision Tree are:

1. The interest rate has the highest level of information gain. Thus, it is selected as the root node.
2. The Total EMI per month feature has the highest number of splitting.
3. Mostly if the interest rate is lesser, then the credit score is ‘standard to poor’.

Below are the decision rules:

- If Interest Rate < 1.13004 or Missing, Month is one of 1, 3, 2 and Credit Mix >= STANDARD then Credit Score = Standard to Poor
- If Outstanding Debt < 3.10396, Interest Rate >= 1.13004 and Month IS ONE OF 1, 3, 2 then Credit Score = Standard to Poor
- If Outstanding Debt >= 3.10396 or Missing, Interest Rate >= 1.13004 and Month is one of 1, 3, 2 then Credit Score = Standard to Poor
- If Num Credit Card < 0.53959, Interest Rate < 1.13004 or Missing, Delay from due date < 1.24286 or Missing and Credit Mix <= GOOD or Missing then Credit Score = Good
- If Outstanding Debt >= 3.17146, Interest Rate < 1.13004 or Missing, Delay from due date >= 1.24286 and Credit Mix <= GOOD or Missing then Credit Score = Standard to Poor
- If Outstanding Debt >= 3.10396 or Missing, Num Credit Inquiries >= 0.73856 or Missing, Interest Rate >= 1.13004 and Month is one of 7, 4, 6, 5, 8 or Missing then Credit Score=Standard to Poor
- If Outstanding Debt < 3.17146 or Missing, Num of Delayed Payment < 0.81162, Interest Rate < 1.13004 or Missing, Delay from due date >= 1.24286 and Credit Mix <= GOOD or Missing then Credit Score = Standard to Poor
- If Total EMI per month < 2.68316 or Missing, Interest Rate < 1.13004 or Missing, Credit History Age < 1.28443, Month is one of 7, 4, 6, 5, 8 or Missing and Credit Mix >= STANDARD then Credit Score = Standard to Poor
- If Total EMI per month < 3.26778, Total EMI per month >= 2.68316 or Missing, Interest Rate < 1.13004 or Missing, Month is one of 7, 4, 6, 5, 8 or Missing and Credit Mix >= STANDARD then Credit Score = Good

- If Total EMI per month ≥ 3.26778 , Interest Rate < 1.13004 or Missing, Month is one of 7, 4, 6, 5, 8 or Missing and Credit Mix \geq STANDARD then Credit Score = Standard to Poor
- If Total EMI per month < 2.17995 or Missing, Outstanding Debt < 3.10396 , Num Bank Accounts ≥ 0.87409 , Interest Rate ≥ 1.13004 and Month is one of 7, 4, 6, 5, 8 or Missing then Credit Score = Standard to Poor
- If Total EMI per month ≥ 4.3478 , Outstanding Debt < 3.10396 , Interest Rate ≥ 1.13004 and Month is one of 7, 4, 6, 5, 8 or Missing then Credit Score = Standard to Poor
- If Outstanding Debt ≥ 3.10396 or Missing, Num Credit Inquiries < 0.73856 , Interest Rate ≥ 1.13004 , Amount invested monthly ≥ 2.59556 and Month is one of 7, 4, 6, 5, 8 or Missing then Credit Score = Good
- If Num Credit Card < 0.81162 , Num Credit Card ≥ 0.53959 or Missing, Interest Rate < 1.13004 or Missing, Delay from due date < 1.24286 or Missing, Changed Credit Limit < 1.12024 or Missing and Credit Mix \leq GOOD or Missing then Credit Score = Good
- If Num Credit Card ≥ 0.81162 , Interest Rate < 1.13004 or Missing, Delay from due date < 1.24286 or Missing, Credit History Age < 1.17492 and Credit Mix \leq GOOD or Missing then Credit Score = Standard to Poor
- If Outstanding Debt < 3.17146 or Missing, Num of Delayed Payment ≥ 0.81162 or Missing, Interest Rate < 1.13004 or Missing, Delay from due date ≥ 1.24286 , Payment of Min Amount is one of YES and Credit Mix \leq GOOD or Missing then Credit Score = Standard to Poor
- If Total EMI per month < 2.68316 or Missing, Num Credit Inquiries < 0.53959 , Interest Rate < 1.13004 or Missing, Credit History Age ≥ 1.28443 or Missing, Month is one of 7, 4, 6, 5, 8 or Missing and Credit Mix \geq STANDARD then Credit Score = Standard to Poor
- If Total EMI per month < 2.17995 or Missing, Outstanding Debt < 3.10396 , Num Bank Accounts < 0.87409 or Missing, Interest Rate ≥ 1.13004 , Payment Behaviour is one of HIGH SPENT SMALL VALUE PAYMENT, LOW SPENT SMALL VALUE PAYMENT, LOW SPENT MEDIUM VALUE PAYMENT, LOW SPENT LARGE VALUE PAYMENT or Missing and Month is one of 7, 4, 6, 5, 8 or Missing then Credit Score = Standard to Poor
- If Total EMI per month < 4.3478 , Total EMI per month ≥ 2.49057 , Outstanding Debt < 3.10396 , Interest Rate ≥ 1.13004 and Month is one of 7, 4, 6, 5, 8 or Missing then Credit Score = Good
- If Outstanding Debt ≥ 3.10396 or Missing, Num Credit Inquiries < 0.73856 , Monthly Inhand Salary < 3.48237 , Interest Rate ≥ 1.13004 , Amount invested monthly < 2.59556 or Missing and Month is one of 7, 4, 6, 5, 8 or Missing then Credit Score = Standard to Poor
- If Num Credit Card < 0.81162 , Num Credit Card ≥ 0.53959 or Missing, Interest Rate < 1.13004 or Missing, Delay from due date < 1.24286 or Missing, Changed Credit Limit ≥ 1.12024 , Payment of Min Amount is one of NO or Missing and Credit Mix \leq GOOD or Missing then Credit Score=Good
- If Num Credit Card ≥ 0.81162 , Interest Rate < 1.13004 or Missing, Delay from due date < 1.24286 or Missing, Credit History Age ≥ 1.17492 or Missing, not_spec_loan_f is one of N or Missing and Credit Mix \leq GOOD or Missing then Credit Score = Good
- If Outstanding Debt < 3.17146 or Missing, Num of Delayed Payment ≥ 0.81162 or Missing, Num Bank Accounts < 0.53959 , Interest Rate < 1.13004 or Missing, Delay from

due date ≥ 1.24286 , Payment of Min Amount is one of NO or Missing and Credit Mix \leq GOOD or Missing then Credit Score = Standard to Poor

- If Total EMI per month < 2.68316 or Missing, Num Credit Inquiries ≥ 0.53959 or Missing, Monthly Inhand Salary < 3.96792 or Missing, Interest Rate < 1.13004 or Missing, Credit History Age ≥ 1.28443 or Missing, Month is one of 7, 4, 6, 5, 8 or Missing and Credit Mix \geq STANDARD then Credit Score=Standard to Poor
- If Total EMI per month < 2.68316 or Missing, Num Credit Inquiries ≥ 0.53959 or Missing, Monthly Inhand Salary ≥ 3.96792 , Interest Rate < 1.13004 or Missing, Credit History Age ≥ 1.28443 or Missing, Month is one of 7, 4, 6, 5, 8 or Missing and Credit Mix \geq STANDARD then Credit Score = Good

8.2 Logistic Regression Model

Logistic Regression (LR), also known as logit model is a type of statistical model used in classification and predictive analytics. The value of the dependent variable is bounded between 0 and 1 due to the probabilistic outcome. A logit transformation is performed to the odds in the Logistic Regression, which is the probability of success divided by the probability of failure. There are three types of logistics regressions which are binary Logistic Regression, multinomial Logistic Regression, and ordinal Logistic Regression.

The Logistic Regression model is run using the Regression node where some properties are set as below:

.. Property	Value
General

8.3 Gradient Boosting Model

Gradient is the term used to describe the error, or residual, that results from model construction. Boosting means to get better. Error can be improved (reduced) progressively by using gradient boosting. Gradient Boosting and random forest are comparable in certain ways, however random forest is a bagging (bootstrap aggregating) approach that mixes the output of various decision trees to get the forecast. To obtain the average forecast across all trees in a bagging technique, trees are typically generated in parallel using a sample of the original data for each tree. On the other hand, predictions made by gradient boosting have a different format. In order to obtain predictions, boosting uses a sequential method as opposed to parallelizing the tree-building process. Gradient boosting is a technique where each decision tree boosts (improves) the error of the previous decision tree by predicting its error (Ayyadevara, 2018).

The Gradient Boosting model is run using the Gradient Boosting node where some properties are set as below:

Series Options	
N Iterations	1700
Seed	12345

8.4 Least-Angle Regression (LARS) model

Efron et al. (2004) introduced least angle regression; an algorithm used in regression for high-dimensional data. The LARS node may effectively generate LASSO solutions by modifying the LAR algorithm, which is useful for choosing the best-fitting model. The LAR algorithm generates a series of regression models, similar to the forward selection method used with regression models but sometimes may be more accurate in predictions. With each stage, a new model parameter is added. Once all parameters have been incorporated into the model, the succession of models comes to an end at the full least squares solution. A significant number of potential model inputs (independent or explanatory variables) are typically present in data mining databases and can be utilized to forecast the value of a particular objective (a dependent or response variable). The LARS node is capable of model fitting and variable selection. The LARS node picks the variables in a continuous manner when used for variable selection, as the coefficients for each chosen variable increase from zero to the variable's least square estimates.

The LARS model is run using the LARS node where some properties are set as below:

Modeling Techniques	
Use Class Inputs	Yes
Intercept	Yes
Variable Selection Method	LASSO
Model Selection Criteria	Cross Validation
Path Stopping Criterion	Maximum Steps
Maximum Steps	600
Cross Validation Options

Figure 8.4.2: Statistical Output of Least-Angle Regression

9 SEMMA: Assess

The performance between the four chosen models which are the Decision Tree (DT), Logistic Regression (LR), Gradient Boosting (GB), and Least-Angle Regression (LARS) are compared using several evaluation metrics, including misclassification rate, accuracy, precision, recall, F1-score, and ROC-AUC.

Based on Figure 9.1, it is observed that the Gradient Boosting has the highest True Positive and True Negative value for both the training and validation sets. The confusion matrices presented in Figure 9.2 describe the performance of each algorithm on training and validation sets. These matrices serve as the basis for calculating important evaluation metrics such as precision, recall, accuracy, and F1-score.

	LARS	LARS	LARS REPREP... Replaceme...			0.1833
	Reg2	Reg2	Regression... REPREP... Replaceme...			0.1858

Figure 9.3: Model Performance

Table 9.1 shows the precision, recall, accuracy, and F1-score for each model. The Gradient Boosting model outperformed the other models with a misclassification rate of 0.1538, and accuracy score of 84.62%. With a slightly different in the misclassification rate, 0.1599, the Decision Tree has an accuracy of 84.01%. The other two models, LARS and Logistic Regression have an accuracy of 81.67% and 81.42% respectively. Apart from that, Gradient Boosting also has the highest precision and F1-score, whereas Decision Tree has the highest recall, followed by Gradient Boosting with the second highest recall value.

Models	DT	LR	GB	LARS
Accuracy	84.01%	81.42%	84.62%	81.67%
Precision	0.8569	0.8327	0.8778	0.8381
Recall	0.8166	0.7864	0.8044	0.7850
F1-Score	0.8362	0.8089	0.8395	0.8107

Table 9.1: Accuracy, Precision, Recall and F1-Score of the Models

Figure 9.4 shows that Gradient Boosting has the highest AUC followed by DT, Logistic Regression, and LARS with the lowest AUC. An excellent model has an AUC close to one, indicating that it has a high level of separability, so the higher the AUC, the better the model.

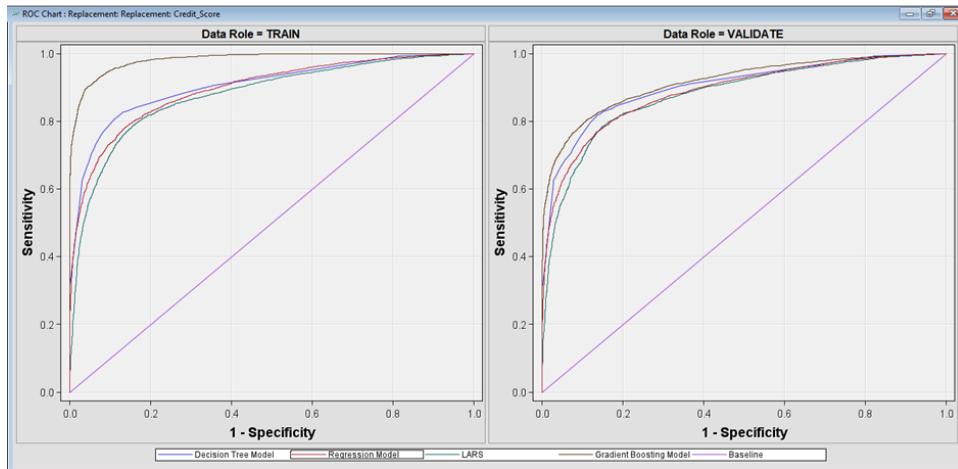

Figure 9.4: ROC Curve

Overall, the Gradient Boosting model is the best model for this credit score classification problem. It has the highest accuracy, precision, F1-score, and AUC as well as the second highest recall value.

10 Conclusion

In the data exploration stage, there are variables of several error types that required data preprocessing and cleaning. They are then modified using different methods such as imputation and transformation, which are illustrated in Table 10.1.

Variable	Data Type Error	Replacement (Y/N)	Imputation (Method)	Log10 Transformation (Y/N)	Other modification

Table 10.1 Data Modification Summary

After modifying, the variables in the initial dataset are reclassified and new variables are added into the dataset. A new dataset is formed with a total of 32 inputs and 1 target variable, with the variable types listed in Table 10.2 below.

Role	Types	Variable Count
Input	Nominal	4
	Interval	17
	Ordinal	1
	Binary	9
Target	Binary	1

Table 10.2 Variable Type and Role Summary

In the Modelling and Assessment Stage, several models are selected to classify the credit score of the customers based on their credit-related information (features) and these models are assessed based on various evaluation metrics as summarized in Table 10.3.

Model Type	Misclassification Rate	Accuracy Score (%)
Decision Tree (DT)	0.1599	84.01
Logistic Regression (LR)	0.1858	81.42
Gradient Boosting (GB)	0.1538	84.62
Least-Angle Regression (LARS)	0.1833	81.67

Table 10.3 Model Types and Performance

The following key findings were discovered during the data exploration phase by examining the relationships between features and target, as well as significant patterns within the modified data. These valuable insights highlight the factors that are closely associated with credit scores, thus allowing us to successfully achieve one of our project goals, which is to identify the key determinants of creditworthiness.

1. The most frequent payment behavior of the borrowers is low spending with small value payments and most of them are scientists.

2. Based on the relationship between the input variables, it shows that annual income and monthly in hand salary both have high positive correlation, followed by loan and total EMI per month. Both relationships are logical as annual income and monthly in hand salary are related to the borrower's income earned. When the loan amount is high, eventually total EMI to repay is high, given that the downpayment is constant. Meanwhile, the interest rate and credit history age have a negative correlation value, indicating that interest rate is lower when the credit history age is higher. This is due to lenders being able to track a lengthier pattern of good credit history of a borrower.
3. From an association standpoint between input variables and target variable using Chi-Square plot, credit mix and payment of minimum amount variables show higher correlation with credit score, which potentially shows greater variable importance in classifying the credit score.

By incorporating these findings into model development, we can ensure that the resulting model captures the important features that contribute to creditworthiness and provides more precise predictions on customers' credit scores.

The interesting findings in modelling and assessing phase are described below.

4. From the decision tree model, variables with the highest important values are interest rate, credit mix and the month. These variables demonstrate a stronger influence on the model's prediction compared to others. However, it should not be treated as a general statement about the variable importance in the real world.
5. In the decision tree model, the interest rate is selected as the root node as it has the highest level of information gain. In terms of splitting, total EMI per month has the highest splitting number, which indicates that the tree considers total EMI per month most informative and has highest discriminatory power for making splits in the data.

In this study, we have developed the credit score classification model based on customers' credit related information and assessed the best classification model by evaluating performance of different models on various metrics. Based on the result, we are able to justify that Gradient Boosting is the best credit score classification model as it provides the best accuracy with the lowest misclassification rate. All objectives of this study are successfully accomplished, including determining the key factors affecting the credit score, building credit classification model and assessing the best models.
